Truck Buying Narrows Down to Four Rival Makers!

Fierce Competition for Supremacy!

Competition in truck selling is now practically limited to four famous makes. That is, among the experienced buyers.

The aggregate resources of these four makers is over $25,000,000. Their yearly output is high up in the millions. Their supremacy is assured. Their guarantees are safe.

Two of these four famous makers build Trucks in excess of five tons capacity. All four build Trucks to haul three-ton loads. In the two-ton field choice is restricted to three makes, and the Velie alone builds a standard one-ton truck.

The three-ton Trucks built by these four famous makers are the best basis for comparative specifications. And because each of these four manufacturers is building the best truck he can, the difference in specifications is not great.

Perhaps the most noticeable difference is in the power of the motor. And here the Velie motor exceeds the average of its three competitors by 6 horsepower, and exceeds that of one of the famous four by 15 horsepower.

In Strength of Frame, three of these four Trucks use a frame 6 inches deep and one a frame 5 inches deep. But the 6-inch Velie frame is reinforced by a 4-inch sub-frame.

The value of this is perhaps not noticeable except on an extremely heavy load or in its general effect upon the long life of the Truck.

The average size of the rear wheel —the wheels that furnish the driving —is 39x4 inches. The Velie, with its 40x5-inch rear wheels, has larger equipment than any of the other three.

This same slight advantage in specifications holds equally true in a comparison of the three two-ton Trucks.

In the one-ton Truck field the Velie shows 25 per cent more power than any of the best known Trucks of this capacity now being built.

Everywhere—as a result of competitive tests between the four greatest American Trucks, the records of which any Velie dealer can show—the Velie Truck is being used by the great corporations, who buy Trucks by the dozen.

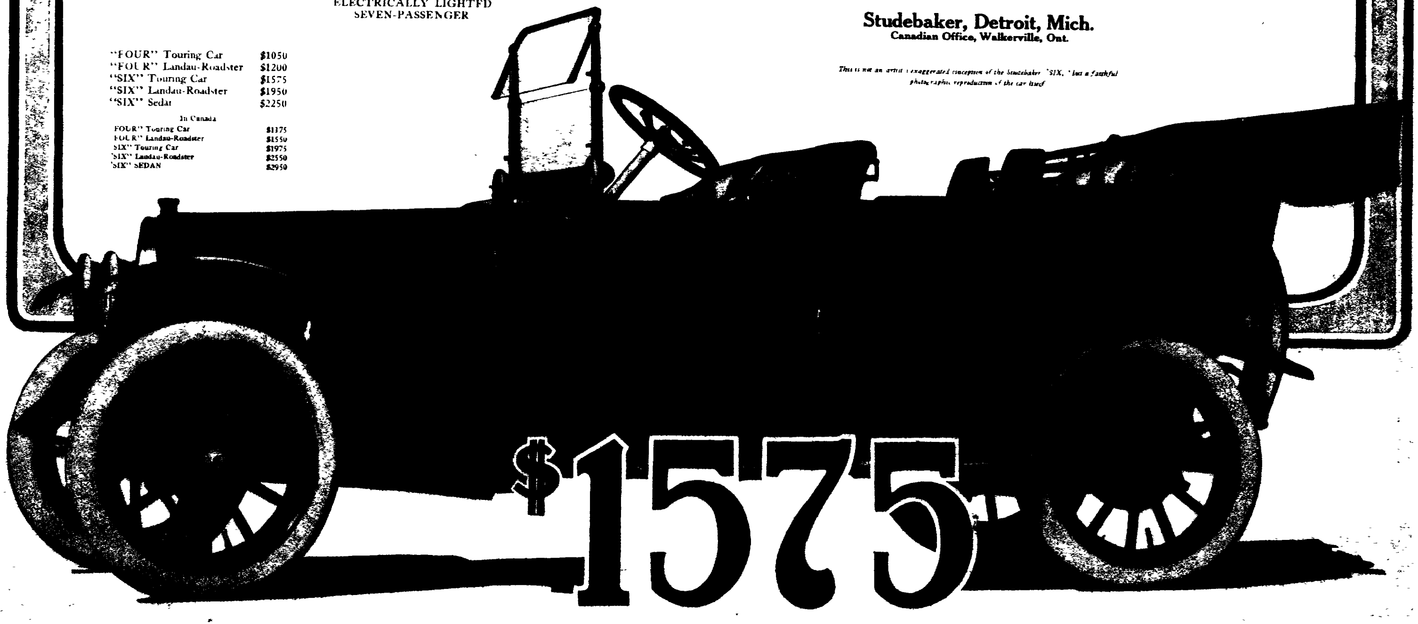
"Buy It Because It's a Studebaker"

At a price lower than the price of any other "Six" in the world.

Studebaker, Detroit, Mich.
Canadian Office, Walkerville, Ont.

This is not an artist's exaggerated conception of the Studebaker "SIX," but a faithful photographic reproduction of the car itself

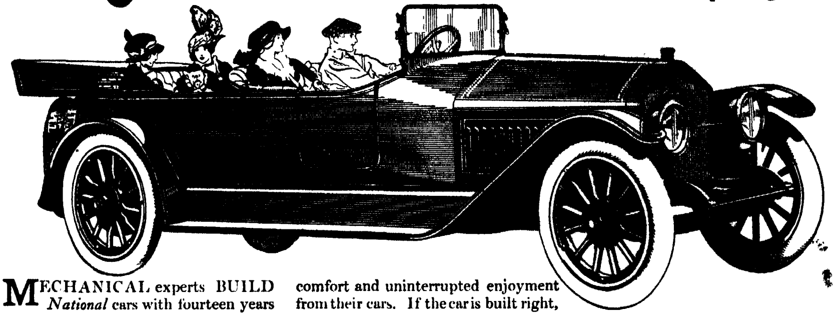


Machinist or Motorist?

You don't have to be a mechanical expert to safely buy a

National Six—$2375

Four and five-passenger



MECHANICAL experts BUILD *National* cars with fourteen years experience to guide them.

But women and men who do not claim to be authorities on machinery BUY *National* cars as safely as though they were experts. Motorists have faith in the company that builds and guarantees *National* cars, because the world-famed signature *National* is not only a name of a car but the mark of quality.

We welcome a detailed analysis of the *National;* we invite you to visit and inspect our factories. But what motorists demand today is service, confidence, comfort and uninterrupted enjoyment from their cars. If the car is built right, if the right materials are put in the right place, if the design is correct and the workmanship good, you can then avoid the work of "going over a car with a fine tooth comb." That way of buying a quality car is obsolete.

You can't find a better built car than the *National* if you use a microscope. We give you all you can possibly demand in a high-grade motor car, and give it to you with complete abandon of worry about what is under the hood or beneath the seat.

Brief Specifications—
***National* Six**

Motor, 6-cylinder, 3¾x5½-inch, cast en bloc. Tire pump, integral part of motor. Clutch, self-contained aluminum cone. Starting and lighting, electric two-unit system. Transmission, sliding gear selective type, three speeds forward, one reverse. Gauge, 56 inches. Oiling, crank-case constant level, force feed, with gear-driven pump. Ignition, high tension, dual magneto with storage battery. Tires, 36x4½. Firestone demountable rims. Air-pressure gasoline feed, generated by small pump in crank-case. Capacity, 23 gallons. Automatic carburetor. Two sets of brakes on 16-inch rear wheel drums. Bevel gear drive through straight line shaft with universal joints and torsion member. Full-floating rear axle. Left-side drive. Access all four wide doors. Single lever in center controls all speeds. Half elliptic springs, front; special *National* construction, rear.

Equipment:--Top complete with side curtains and boot, ventilating rain vision windshield, extra Firestone rim, electric lighting and starting systems, 12-inch double bulb electric headlights, electric license tail light, Warner speedometer, electric horn, tools and jack.

"You don't have to raise the hood"

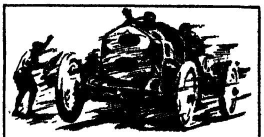
NATIONAL owners have learned that we build *whole* cars—the name *National* is their guarantee. Every *National* car is built as a *unit*—every mechanical part operates harmoniously to produce satisfactory *results*. You leave the responsibility for its mechanical construction to our experience—forget that there are gears and mechanical parts in the car Just rest in comfort and enjoy your ride with absolute confidence in your car.

You can buy over telephone

NATIONAL owners buy performance and not specifications—they can buy their new *Nationals* over the telephone. We sell our experience, ability, responsibility and our guarantee—not a mere job of wheels, axles, gears and parts. That's why you don't have to raise the hood to buy a *National*, you know no better is made.

Lavish in comfort

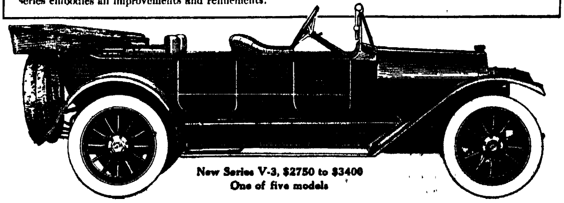
THIS new *National* embodies all our internationally recognized principles of superiority. Beautiful, economical, efficient and lavish in comfort — this car is the climax of the *National's* success in car building since its pioneer beginning. It marks a most coveted improvement in motor car designing. It is the one car that harmonizes from end to end—a symmetrical creation that is distinctive and essentially practical.



REMEMBER

When you say "*National*" you are talking about the world's champion car. The *National* is the World's Stock Champion; International Champion 500-mile race record holder; Fastest Mile for stock car record holder, etc. No other has ever equalled the *National* in actual performance and demonstration of its quality, power, speed, reliability and sureness.

The *National* 40 with its marvelous history, needs no introduction. This is our staple car—the highest achievement in automobile building. Here is the best all-around motor car ever made. This is the third year for this successful car in all its essential features. This new series embodies all improvements and refinements.



New Series V-3, $2750 to $3400
One of five models

Mitchell Sixes

Products of Long Experience

This company has been building popular priced sixes longer than any other concern in this country. Hence the sixes we offer are the product of many years of experience and in no sense experiments.

The *Mitchell Little Six,* which was known as the "Baby Six" in 1912, is, in our opinion, the most logical investment in the automobile market. It is not only the sensible compromise between big and little power and passenger capacity, but it has everything that any high-priced car can offer you.

It has quality that insures long life. It has the style of beauty that the exacting mind demands. It has as much speed and power as any person can desire. It will hold its place in any company and look classy and work perfectly for several years to come. Its equipment is complete, and details thereof sterling in character. The price, $1,895, brings this smart car to you ready for instant use. There is nothing left for you to buy—no extras—no appurtenances.

The *Mitchell Big Six* is the largest and best car at the price that has ever been produced. It is built along the same lines as the Little Six, save that it has 144-inch wheel base, somewhat larger tires, greater passenger capacity. Yet the quality of the two are identical. The equipment is precisely the same—the outward beauty similar. For a big family car the Big Six has no equal in America and there is nothing as good for less than $3,500 or $4,000. The price of the Mitchell Big Six is only $2,350.

The *Mitchell Four* is intended for those who feel that they cannot afford either of the Sixes. It is the only four-cylinder car we make. We build it to meet the demand of those persons who still like a four-cylinder car of class at a popular price. It has the same equipment as the other two cars and sells for $1,595. We want you to look this car over minutely and then ask yourself if there is a four-cylinder car at anywhere near the price that can compare with this one in any detail.

Here is the Equipment for all the Mitchell Models Which is Included in the List Prices, as Given:

Electric self-starter and generator—electric lights—electric horn—electric magnetic exploring lamp—mohair top and dust cover—Tungsten valves—Jiffy-quick-action side curtains—quick-action two-piece rain vision wind shield—demountable rims with one extra—speedometer—double extra tire carrier—Bair bow holders—license plate bracket—pump—jack—and complete set of first-class tools

Specifications of the Three Great Mitchell Models:

MITCHELL LITTLE SIX—Fifty horse-power—132-inch wheel base—36x4½-in. tires—two or five passenger capacity	**$1,895**
MITCHELL BIG SIX—Sixty horse-power—144-inch wheel base—37x5-in. tires—seven passenger capacity - - -	**$2,350**
MITCHELL FOUR—Forty horse-power—120-inch wheel base—4 cylinders—36x4½ in. tires—2 or 5 passenger capacity	**$1,595**

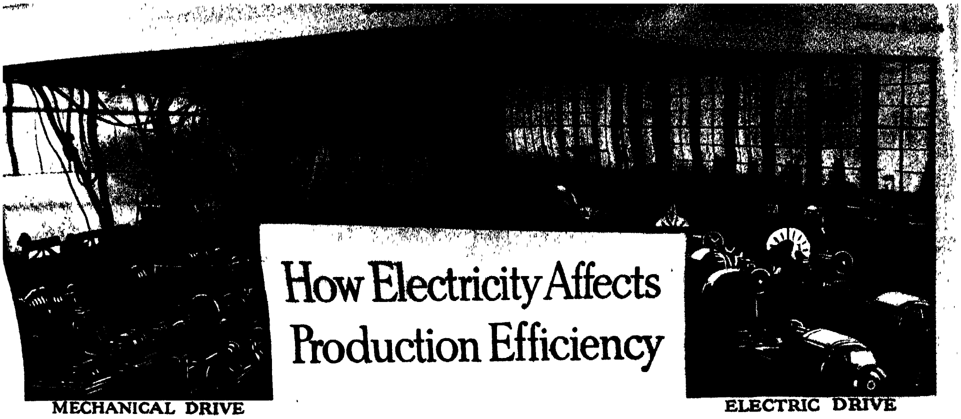
Eighty Years of Faithful Service to the American Public



How Electricity Affects Production Efficiency

MECHANICAL DRIVE

ELECTRIC DRIVE

WHEN the big belt at the end of a long line of shafting snapped with a disagreeable report, throwing a half dozen machines out of commission, the manager of the busy Indiana manufacturing plant turned to the Vice President of the corporation with an exclamation of disgust.

"These things always happen on the wrong day," he said.

The Vice President rather unexpectedly smiled. "Maybe it happens just at the right time," was his comment as he left the place. In ten minutes he was back with the President.

"What you see here," he said to the President with a glance at the halted work, "illustrates better than an hour of talk the immediate need of this concern. The board was satisfied to get in that Curtis turbine and every one agrees that the new electric power was a big thing for the works, but we're away out of date on the rest of the equipment. You know what the line shafting costs. You know that the power loss in transmission is somewhere between 25% and 40%. You know how the whole contrivance of line shafting cuts out light, how dirty it is, how badly it effects insurance rates and how dangerous it is. We're none of us likely to forget that accident to Wincher in September. You know that we're paying for all this wear and tear and wasted power even when only a few of the machines are in use. This morning we have a good, clear showing of what happens to this whole bunch of machines when anything goes wrong with the belting."

"How would you fix it?" demanded the President.

"I'd settle the difficulty by cleaning out the whole mess of shafting and giving individual motor drive to each machine. Then only the active machines would be using power, and the stopping of one would not interfere with any of the others. Now we have to start up the whole of a wasteful and dangerous transmission system to move one machine. With individual drive each machine is independent, and a wide margin of waste is cut out every day. Into the bargain the output would be boosted, man for man, by the modern system. I'm no technical expert, but I should say we were bound to do from 15% to 20% more work with the same force, not counting the salary saving from the simpler machinery system."

As the thing turned out that accident had happened at exactly the right time. The next board meeting took up the problem and a local electrical engineer's figures showed that motors and installation would figure much below the theoretical cost. The actual showing fourteen months after the installation was that the saved percentage more than covered the cost of the change, with an outlook of certain results in economy, while the increase in output quite justified the Vice President's prediction.

In small plants and in large plants, from coast to coast, the newer, cleaner, safer electrical methods are transforming the production problem; first, by improving the physical conditions of plants in the matter of light, by eliminating cumbersome and wasteful transmission machinery, by economies in actual power consumption per machine unit; second, by increasing the working efficiency of each machine unit and each human unit. In refinery or in machine shop, in mill or in printing plant — in any place where power is used; the efficiency and economy of electrical methods are being proved.

Whatever your problem may be, however large or small, it will pay you, in saved money and saved effort, to consider electrical help.

Take up the matter today with your electric power and light company or any General Electric Company agent in your vicinity. You will find them more than glad to co-operate with you, and no matter how complex your problem may be they have at their command the service of any part of our organization that may be most useful to them and to you.

Edmund Beecher Wilson

The New President of the American Association for the Advancement of Science

By Marcus Benjamin, Ph.D.

IT is now eight years since the American Association for the Advancement of Science turned its steps southward for its annual meeting. Then it met in New Orleans under the presidency of Calvin M. Woodward, eminent for his educational work in the technical department of Washington University in St. Louis. This year it meets in Atlanta with Edmund B. Wilson, who holds the Da Costa chair of zoology in Columbia University, as its presiding officer.

Edmund Beecher Wilson is the son of Judge Isaac G. Wilson and Caroline Clark Wilson, and was born in Geneva, Ill., on October 19th, 1856.

After the usual preliminary schooling he was prepared for college and studied for a year each at Antioch and Chicago; then entering Yale he was graduated at the Sheffield Scientific School in 1878 with the degree of Ph.B. A country boy, he early developed a fondness for nature, the study of which has been the dominant influence of his life. Choosing biology therefore as the subject to which he determined to devote his career, he went to the Johns Hopkins, where under the influence of such inspiring teachers as Newell Martin and Brooks he spent three years, taking the degree of Ph.D. in 1882. A year abroad followed, during which he studied in the laboratories in Cambridge, and Leipsig, and also at the Naples Zoological Station under the famous Dorhn.

On his return to the United States he entered on his vocation as a teacher and lectured on biology at Williams College during 1883-'4 and at the Massachusetts Institute of Technology during 1884-'5. He then accepted an invitation to Bryn Mawr College, where he filled the chair of biology. In 1891 he was called to Columbia as adjunct professor of biology, and three years later was advanced to the full possession of the chair of invertebrate zoology, created for him, which he then held until 1897, when he was transferred to the Da Costa chair of zoology. He also served as member of the University Council at Columbia during 1901-03, and as dean of the faculty of pure science for the years 1905-06.

Wilson's primary interests have always been in the field of embryology and his original investigations which were begun at Johns Hopkins University have been connected chiefly with the study of animals as living things. At first his researches were concentrated on germ cells and directed attention to the study of the laws of normal development from the standpoint of the cell. These he followed with valuable contributions to problems of mosaic development, prelocalization, and differentiation in the egg. Returning more recently to the mechanism of the cell, his researches on the structure of protoplasm, on the history of centrosome, aster and karokinetic figures, and on the chromosomes with special reference to questions of heredity and sex, have occupied his attention.

His many papers, which according to competent authority have had "a wonderfully stimulating effect on biological research throughout the world," have been carefully worked up into harmonious relations with the modern aspects of the fundamental problems of biology, and were given to the world in 1896 in book form with the title "The Cell in Development and Inheritance," which his colleague, Prof. Gary N. Calkins, refers to as "one of the most widely read of modern technical scientific works."

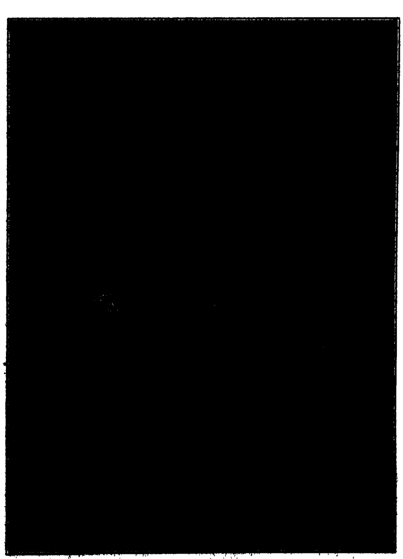
In addition to the foregoing he is the author of addresses and of various minor works in zoology, embryology, and cellular biology. His contributions in book form include (with William T. Sedgwick) "General Biology" (1887); and an "Atlas of Karyokinesis and Fertilization" (1895).

His brilliant researches early gained recognition for him and academic honors have been gladly conferred on him. In this country the three universities at which he studied, Chicago (1901), Yale (1901), and Johns Hopkins (1902) have given him the degree of LL.D., while abroad he has received the degree of Sc.D. from Cambridge (1909) and that of M.D. from Leipzig (1909).

In addition to membership in the American Society of Naturalists, the American Society of Zoologists and the Society of Experimental Biology and Medicine, he is an officer of the New York Academy of Science, a fellow of the American Academy of Arts and Sciences, and since 1899 a member of the National Academy of Science. He holds honorary membership abroad in the academies of science in Holland, Belgium, Bavaria, and Rome (dei Lincei) and also of the Linnean and Royal Microscopical societies.

His connection with the American Association began with his election to membership at the second New York meeting in 1900, at the close of which he was advanced to the grade of Fellow. He affiliated with the section on Zoology, becoming its presiding officer in 1907, when he delivered an address on "Recent Researches on the Determination and Heredity of Sex."

In its selection for a presiding officer for the Atlanta meeting the American Association for the Advancement of Science is indeed most fortunate. Seldom has a more ideal choice been made, for Wilson by right follows in succession to that splendid group of men who from Agassiz and Dana to Cope and Jordan, have been the glory of American science.



Edmund Beecher Wilson, president of the American Association for the Advancement of Science.

Prolonging the Life of Steel

EXHAUSTIVE research experiments have lately been carried out to try if possible to lengthen the life of iron and steel. These experiments consist in the addition of some other metal or chemical element to the iron during the smelting to form an alloy; such elements for example as copper, silver, lead, manganese, silicon, arsenic, aluminium, nickel and tin being added. The more common method of preserving steel structures has consisted in the application of a protective coating of paint or galvan to the steel, the coating acting as an excluder of air and water, and by this means preventing the rusting of the iron indefinitely.

It is remarkable that the addition of certain elements to iron makes the resulting alloy rust and decay more quickly than pure iron. Silicon is a good example of this kind of reaction; if three pounds of silicon be alloyed with nine hundred and ninety-seven pounds of iron, the alloy will rust twenty per cent more rapidly than the pure iron.

The general results of alloying steel with the other metal show that copper and nickel are the best metals to add to the steel to give increased durability. Nickel is prohibitive on account of its price for general commercial uses.

Copper added in small quantities greatly prolongs the life of iron. Very small quantities are needed to effect this result. If to one thousand pounds of iron, two pounds of copper be added, the resulting alloy will dissolve away in acid only one tenth as fast as pure iron does. And in the atmosphere the corrosion will be only one third as rapid. An increase in the copper up to seven per cent of the alloy does not increase the power of the iron to resist corrosion Two tenths of one per cent of copper will yield as good an alloy for resisting rust and corrosion as does seven per cent, and the resulting alloy is less expensive on account of the small amount of copper required

The durability of this alloy has been demonstrated by some very beautiful experiments, performed in Pittsburgh, Pennsylvania, by Mr. D. M. Buck, and by Prof. C. E. Burgess and J Aston of Wisconsin University.

Mr. Buck's experiments were carried out in a practical way by erecting sample roofs made of pure iron and others made of the alloy containing two tenths of one per cent of copper. These sample roofs were distributed both in the city in the region of the coke ovens and in the rural districts around Pittsburgh, and the rate of corrosion was noted carefully and the time recorded The copper alloy roofs were in good condition when the pure iron had completely corroded and had fallen away. The results show also that the metals are less attacked in the rural districts than in the city. This is to be expected and is no doubt due to the carbon and acid fumes present in the city atmosphere.

The experiments carried out at the University of Wisconsin were not carried out on so large a scale as Mr. Buck's, but they confirm very clearly his results Their experiments show that the addition of many metals, such as silver, which in themselves are too expensive for general use, have the same effect as small quantities of copper in prolonging the life of steel.

Their results also show that no very reliable data can be obtained by the accelerated acid test which will indicate the possible length of life for the steel under ordinary weather conditions.

An Echo of the Hubbard Expedition to Labrador

DILLON WALLACE, whose book "The Lure of the Labrador Wild" is a record of the adventures of himself and Leonidas Hubbard, Jr., during their exploration of the interior of Labrador in 1903, in which Hubbard died from starvation and exhaustion and the author narrowly escaped the same fate, has just returned from a second hazardous journey to the same region The purpose of this trp was no less sentimental than that carried out in 1905 by Mr. Hubbard's widow, who, besides continuing her husband's explorations, proved to the world the feasibility of his projected route. Wallace revisited the headwaters of the Susan River, discovered during the original expedition, in order to erect a bronze tablet at the place where Hubbard died. Unluckily the tablet was lost from his canoe *en route*, and Wallace accordingly carved his comrade's epitaph on a rock.

Retrospect of the Year 1913

Civil Engineering.

A RETROSPECTIVE view of the field of civil engineering, especially if it be taken from the American standpoint, brings to mind, at once, the Panama Canal the greatest civil engineering work of all time. In the annals of the canal the year 1913 will be memorable as having witnessed its practical completion During the first nine months of the year Gatun Lake was filling with water, on October 10th President Wilson threw an electric switch and blew up the Gamboa Dike admitting the water to the Culebra cut, and a few weeks previously a dike at Miraflores was blown up, admitting the Pacific waters to Miraflores locks A heavy force of hydraulic dredges has cut through the Culebra slides and is now engaged in clearing up the canal prism at the cut On September 26th a Government tugboat made the first passage of Gatun Locks Subsequently, whole fleets of dredges and their accessories made the passage both of the Gatun and the Miraflores and Pedro Miguel locks. Early in 1914 the canal will be in such shape that, if it were desired, the largest ship in the world could be sent through from ocean to ocean The formal opening will take place in January, 1915, when a vast international fleet, headed by the old battleship "Oregon," will make the transit from ocean to ocean It was a great feat to build any kind of a canal at Panama—to build a canal of this magnitude and complete the job, in spite of 30,000,000 yards of unlooked for excavation, due to slides, etc, one year ahead of the specified time, is a magnificent performance. The past year has been one of great progress on the New York State Barge Canal, and it looks as though within about two years' time it will be possible for 1,000-ton barges to pass between the Great Lakes and the Atlantic by way of the Hudson River. A most important waterway and a competitor of the State Barge Canal is the St Lawrence Ship Channel, between Montreal and Quebec, a distance of two hundred and twenty miles Here the Canadian government is rushing work upon a 35 foot channel A depth of thirty feet has already been obtained over this distance The Cape Cod Canal, 25 feet deep, 150 feet wide and 13 miles long from Buzzards Bay to Bonstable Bay, will be opened in June, 1914 This waterway will render available for 25,000,000 tons of shipping annually a safe inside route, as against the dangers of the outside route through Vineyard Haven Sound and around Cape Cod The vast scheme for bringing the Catskill Mountain water to New York has made great progress during the year The Ashokan dam has been completed, the greater part of the 92-mile acqueduct is built, the water being now available for discharge into Croton Lake, and excellent progress has been made upon the deep distributing tunnel beneath New York, which, in places, reaches a depth of over 750 feet The New York system of dual subways, another vast engineering work, has been pushed so vigorously during the year that two or three of the main sections will soon be in operation or within measurable distance of opening This work will practically treble the existing facilities, and the probabilities are that, within three or four years' time, a greater part of the system will be in active operation. After six years of labor, the enlargement of the Assuan dam on the Nile, Egypt, has been finished The dam, which is 1.21 miles in length, has been raised 16.6 feet in height and increased in thickness by about sixteen feet, and thereby the volume of water stored has been increased from 35,300,000,000 to over 81,000,000,000 cubic feet. The benefits conferred upon Egypt by irrigation are to be repeated beyond the Red Sea in Mesopotamia, where the engineer who is mainly responsible for the Egyptian improvements is now developing and constructing a system of irrigation which promises to restore to that storied land much of its one time fruitfulness and prosperity. The great works of irrigation being carried by the United States Government in the West and the Middle West have, one by one, been completed, and when some adjustment of the rates and time of payment have been made, there is no question that the full predicted benefits of this great work will be realized. Next to the Panama Canal, the engineering work which has attracted greatest attention in this country during the year has been that of the control of the Mississippi River. The devastating floods have merely served to prove that the regulation of this river can be secured only when the whole co-ordinated scheme of revetment and levees, as planned by our army engineers, has been completed. If the staff and the large working plant at Panama were removed to the Mississippi Valley and the whole job placed under one-man control, and the necessary funds made available, the problem of the Mississippi Valley would be easy of solution

Naval and Military.

The opening of the year 1914 finds the United States in the humiliating position of a third-rate naval power—third rate in so far as the strength of its first fighting line is concerned This is due to two things. First, the revolution in naval rating which has been brought about by the advent of the "dreadnought," and second, the disposition of congressmen to play politics with naval policies and cut down national in favor of local appropriations. There is one first-rate power—Great Britain with forty-two dreadnoughts built and building; there is one second rate power—Germany, with twenty-six such ships built and building; there are three third rate powers—the United States, France, and Japan, respectively, with 12, 11 and 10 dreadnoughts built and building. If we rank third-class in material there is some consolation in knowing that we rank absolutely first-class in the high quality of the officers and men of our navy Moreover, such dreadnoughts as we possess are fully the equal, ton for ton of displacement, of any ships in the world. With the exception of the British navy, which has more than doubled the accuracy of its fire by the introduction of the fire-director system of Sir Percy Scott, our shooting is believed to be as good as that of the other leading navies. Let us take such comfort from this belief as we may—the disquieting fact remains that in ships of the line we are third-rate, and in shortage of torpedoes at the very bottom of the list! There has been a steady increase in the size of ships and the guns they carry. Great Britain has gone up to 28,000 tons, Germany to 26,000 tons, and we have two ships on hand, the "Pennsylvania" and her sister, which are of from 31,000 to 32,000 tons displacement. The multiple-gun turret finds increasing favor The United States is placing the three-gun turret on the "Nevada" and "Pennsylvania" classes. Italy has already put in commission her first three-gun turret ship, the "Dante Alighieri." Russia and Austria are using the same turret; but England, Germany, and Japan are holding back; apparently, they still believe that two guns in a single turret is the maximum number that can be used to full efficiency. France, on the other hand, is building several dreadnoughts which mount twelve guns in three four-gun turrets; and the French, by the way, are exceedingly clever and successful in their designs of ordnance. The multiple-gun turret greatly assists the spotter; simplifies fire control; and secures a very considerable reduction in weights. Certainly the most remarkable ships of the year are the five British battleships of the "Queen Elizabeth" class, whose contract speed is to be 25 knots, and their armament eight 15-inch guns. The builders of the turbines assure us that they look for 27 knots in these ships. Meanwhile our own navy sticks to 21 knots as a maximum speed. Which is right? Time alone can tell. England, Germany, and Japan are still building battle-cruisers with speeds of 28 to 30 knots. Japan will soon have four of these ships, carrying among them thirty-two 14-inch guns, afloat on the Pacific. In the event of war they will constitute a knotty problem for our Board of Naval Strategy at Washington. An interesting development has been the launching by Great Britain of a "destroyer of destroyers," as she was called by the First Lord, a ship of 3,500 tons and 30 knots speed. On the other hand, the Germans have built for Russia a destroyer, the "Novik," which made 37 knots on trial, and 36.2 knots for six hours of that trial—and so it goes. Altogether, the year 1913 must be considered as finding the naval-diplomatic situation as regards this country in a critical condition; with its navy sunk to the third-rate rank, at a time when the administration is adopting a policy with regard to neighboring States, which, for audacity and grave portent, has never been equaled in the history of the country.

The Merchant Marine.

Judged from the standpoint of construction, the two outstanding features of the past year are, the continuous increase in the size of ocean steamships and the great amount of thought, labor, and expense, which have been devoted to finding the best type of motive power. Last year was notable in the annals of the merchant marine as witnessing the advent of the first 900-foot ship, the "Imperator" which is 909 feet in length, 98 feet in beam, and displaces, at maximum draught, some 58,000 tons. The present indications are that the big ships of the future of her class will be of moderate speed, say 23 knots, this being the assigned speed of the new "Aquitania," 901 feet in length, which will enter this port during the summer of this year, flying the Cunard flag. The year witnessed the launch of the "Vaterland," sister to the "Imperator," 940 feet in length, and the laying down of another ship of similar dimensions. The application of the Diesel engine to marine propulsion has made steady strides during the year. The "Hagen," propelled by Diesel engines of 2,300 horse-power, made a very successful maiden voyage to this port, and later there came the "Wotan," a large tank steamer 404 feet in length, and capable of carrying 7,680 tons of oil, which is driven by Carels-Diesel engine of 2,900 horse-power (steam engine rating). The builders of this engine have such confidence in its reliability that they have put the whole of the power into a single engine driving a single propeller. During a recent test before marine engineers and representatives of the technical press in this city, this big unit, the largest Diesel marine engine yet built, was run at maximum revolutions with a remarkable absence of vibration, and the reversing from full speed ahead to full speed astern was done in eight to ten seconds, a truly wonderful performance. Rivaling the Diesel engine in its interest is the marine transformer or transmitter, designed in its various forms to reconcile the high speed demands of the turbine with the low speed demands of the propeller, if both are to secure their highest efficiency. In this country, the Westinghouse helicoidal mechanical gear has shown an efficiency of something over 98 per cent, and it has been fitted on the collier "Neptune" of 19,300 tons displacement. In addition to the steam economy due to the use of high-speed turbines, its introduction would secure a great saving in weight, both in the engine and the boiler plant. These are the economies aimed at in all transmission gears. The "Jupiter," sister to the "Neptune," has been fitted with an electrical reduction gear, consisting of a generator delivering current to motors on the propeller shafts. This ship is now undergoing trial. Parsons, in England, has fitted mechanical reduction gears to several cross channel steamers and large economies have been secured. The German Foettinger gear was submitted to a 14-day test at the Vulcan Works, at loads of from five thousand to ten thousand horse-power, during which an efficiency of 90 per cent was secured; and this gear is being installed on several large German steamships. There was completed for the Great Lakes service in November of this year at Wallsend-on-Tyne, England, the "Tynemount," a freighter of 2,400 tons capacity, which has a most interesting drive, consisting of two six-cylinder Diesel engines direct connected to three-phase generators, which furnish electric power for an induction motor mounted directly on the propeller shaft. This is the first large commercial ship to carry an electric reduction drive, and its performance will be watched with keen interest. The "Titanic" disaster has resulted in the formation of an international committee which is now sitting in London to determine the question of interior safety construction for ships, the number and character of lifeboats they shall carry, and the various protective devices, in the way of wireless telegraphy and other apparatus, designed to protect the life of the passenger at sea. There is no question that the whole subject will be most thoroughly and conscientiously thrashed out at this conference, and an entire revision and improvement of existing rules will be secured.

Electrical Engineering.

Although its inception was prior to 1913, the active work of the recently organized Society of Electrical Development falls within the past year, and marks one of its most important outgrowths. The object of this society is to introduce electricity more widely, and to infuse a new spirit of co-operation in the business of selling electricity and electrical goods. Probably the most promising electrical event of the year is the development of the nitrogen lamp. This is a tungsten lamp filled with nitrogen gas, in which the filament may be heated to a much higher temperature. In the large units of 4,000 candle-power and over it shows an efficiency of 0.4 to 0.5 watt per candle-power. Smaller units using 10 amperes at 4 or 8 volts give an efficiency of 0.6 to 1, or even 1.25 watts per candle. Lamps for the standard 110-volt circuit will produce a thousand candle-power and over at 0.5 watts per candle. It is found difficult to produce nitrogen lamps in smaller units owing to the cooling effect of convection currents in the gas. The lamp produces a light that is closer to daylight than any other except the Moore tube filled with carbon dioxide. Other developments in lighting are the Cadmium lamp, which is similar to the mercury vapor lamp, except that cadmium is used instead, to produce a light similar to daylight, and the so-called "cold" light for stereopticon and kinetoscope work. It consists of a series of tungsten lamps which are successively lighted with current at super-voltage, giving flashes of intensely white light that come with such frequency as to give one the impression of a continuous light. Thus, while the heat effect of the electric current is dissipated over a great area, the luminous rays are concentrated in a very small point of space. The use of electricity on the farm for light and power is steadily increasing. Much has been done with intensive culture, not only under the direct influence of electricity, but indirectly by the use of electric pumps for irrigating purposes. In England experiments have been made to determine the influence of high frequency currents upon the growth of chickens, and the results are truly astonishing. Chickens living in the electrified zone in five weeks reached the weight of normal chickens of three months. Because it is a young branch of electrical engineering, there is a great deal to be said annually about the progress of wireless telegraphy. Early in the year communication was established for the first time directly between Germany and the United States. Several new stations have been built or are building for transatlantic wireless service. During the fall wireless telegraphy gave us another demonstration of its importance to navigation, when the "Volturno," afire and fearing immediate destruction in a storm, summoned a rescue fleet by wireless telegraphy, which arrived in time to save a large part of the crew and passengers. To aid the mariner in finding his way across the ocean, wireless signals are sent out daily from the Eiffel Tower in France and from the Arlington station in this country. Wireless telegraphy is being used on trains to permit of communication with stations along the line. Wireless or induction train signal systems are being tried out on some lines. Considerable progress has also been shown in wireless telephony. Spoken messages were sent 600 miles from Rome to Tripoli. At this late date it seems remarkable that material progress should have been made in telegraph and cable systems. During the year a system has been devised which permits of sending the regular dot and dash signals over cable lines and relaying them automatically over land lines. Railroad electrification also shows material progress. For instance, the Chicago, Milwaukee and Puget Sound Line is electrifying 450 miles of its main line between Harlowtown, Montana, and Avery, Idaho. The Norfolk and Western Railroad is electrifying the Bluefield Vivian section, 85 miles long, over which sixty-five thousand tons of coal are handled daily. The Pennsylvania Railroad has announced that it will extend its electrified zone from New York to Elizabeth, and this is probably but a step toward electrification all the way from New York to Philadelphia. Recently a commission appointed by the city of Melbourne, Australia, to determine the best system for its suburban railways, covering about 300 hundred miles of steam and railroad tracks, reported that the direct current system showed a material advantage over single-phase alternating in first cost and also in the annual cost of operation.

Astronomy.

By far the most important astronomical announcement of the year came from Prof. George E. Hale, director of the Mount Wilson Solar Observatory. It will be remembered that some years ago Prof. Hale discovered the Zeemann effect in sun spots, thereby conclusively proving that sun spots must rotate and establishing a field of magnetic influence on the sun. Even more important was the later discovery to which we refer which is nothing more or less than the fact that the entire sun may be regarded as a rapidly rotating magnet.

It has long been known that the conspicuous star cluster in the Pleiades is accompanied by faint nebulosities. Until the work of Mr. Slipher at the Lowell Observatory, nothing was known of the real nature of these faint clouds of light. Very long exposures revealed to Mr. Slipher a distinct spectrum quite different in character from that of any previously known nebula. He showed that the brighter parts of the nebulosity of the Pleiades shine with light which is exactly similar in spectroscopic character to that of the brighter stars of the cluster. It is supposed accordingly that the nebulosity in the Pleiades consists of opaque matter, perhaps of meteorites or fine dust which accompanies the stars of the cluster and shines by their reflected light.

On the night of August 13th, 1911, the third satellite of Jupiter, Ganymede, passed directly in front of a star of the seventh magnitude in the constellation Virgo, and for observers in the southern part of the earth, actually hid the star for more than four minutes. The circumstances of this remarkable occultation were carefully calculated in advance by Banachiewicz. It appeared that the best observing stations would be in South America. Dr. Ristenpart, a German astronomer of distinction, set about the organization of observers throughout Chile. Ganymede is much smaller than the earth, and its shadow is only a little more than four thousand miles in diameter. As Jupiter and its satellite moved, this "shadow" crossed the earth, its center, passing over the southern extremity of South America, a little north of the Straits of Magellan, while its northern limit reached barely to the boundary between Chile and Peru. By comparison of the duration of the occultation as seen from different places, it was possible to obtain very accurate information regarding the size and shape of the eclipsing body. On the basis of the many visual observations made under Dr. Ristenpart's direction, it seems necessary to assume that the satellite like Jupiter itself is flattened at the poles; for otherwise the calculated length of the occultation at the northernmost station, where the star appeared to pass just inside the satellite's disk, should have been much longer than the observed time. Dr. Ristenpart concluded that the equatorial diameter of the satellite is four thousand seven hundred miles and the polar diameter four thousand three hundred miles, so that it is a little more flattened in proportion to its size than Jupiter itself.

Comets are no longer the astronomical curiosities they once were. Three or four are discovered with the aid of the telescope or the camera every year, and 1913 proved no exception. The principal comets were those of Schaumasse, discovered on May 7th at Nice; Metcalf, discovered on September 1st; Neujmin, discovered on September 5th; Delavan, discovered on September 26th and recognized as a return of Westphal's comet of 1852; Tinner, discovered on October 23rd and identified as a return of the third comet of 1900; Delavan, mentioned on another page.

Steam Railroads.

So far as America is concerned, development in steam railroads during the past year have been strictly along those lines which during the past two or three decades have been strongly characteristic of American railroad practice. To-day, we are carrying freight, not only at a much lower rate per ton per mile than any railroad in the world, but even at a lower rate than similar freight is carried for the same distance on the cheap waterway transportation systems of Germany. This result is largely due to our greatly increasing the size of the individual train unit. Locomotives have grown to be several hundred tons in weight; fifty tons has become the standard freight car capacity, and cars of seventy-five and even one hundred tons are in the making or are seriously proposed. The matter of better rails is still a burning question, to which both the railroads and the manufacturers are giving closer attention than they are perhaps to any other product in the heavy manufactured steel trade. The future promise of the railroads getting absolutely reliable rails that will stand up under winter and spring service, lies in the new electric steel making process, which the United States Steel Corporation is trying out on an extensive scale, as explained and illustrated in our issue of June 7th, 1913. The advantage of the electric over the Bessemer and basic Open-Hearth processes are that it secures a more complete removal of oxygen; an absence of oxides; an absence of segregation; the practically total elimination of sulphur and phosphorous—with the result that a very reliable rail is secured. In this connection, it should be noted that, during the year, there has been a wonderful growth of the "Safety First" movement, the importance of which has come to be thoroughly appreciated, not merely by the management, but by the employees. The disastrous wrecks on the New Haven Railroad, to which we gave so critical attention in 1912, were followed by other wrecks in such quick succession, as to convince the nation at large and Congress in particular, that legislation was necessary. The Interstate Commerce Commission is being given the necessary legal status to enable it, not merely to advise, but enforce its recommendations—a wise provision if the delegated authority be exercised with discretion. The automatic stop, thanks largely to the New Haven disasters, has been thrust into the prominence which it merits, and many of the keenest minds, both expert and lay, are being devoted to the production of a stop which shall be thoroughly practicable. That it is the finest safety device ever devised for the protection of railway travelers is proved by the record of the Interborough Railroad where, during several years of operation on express trains, under a headway of one minute and forty-three seconds, there has been only one failure out of 277,846 movements. In locomotive construction, the noticeable developments have been the increased use of superheaters and the tendency to regard the simple, superheated locomotive as the best all-round machine for future use. Great interest was aroused by the production of the first Diesel-engine locomotive, a powerful engine, built for express service, containing a driving engine coupled to the driving axles, and an auxiliary engine working independently of these. The trials are now being carried out, and we understand that the engine has fulfilled all expectations as to its hauling ability. It is too early, however, to make any definite statement as to the permanent usefulness of this type With the increasing size of the locomotive has come a corresponding demand for mechanical stoking, the work of feeding the fuel to the huge modern boilers being more than one man can accomplish. Several types are being tried and in some cases good results have been secured Undoubtedly mechanical stoking has come to stay

Aviation.

A broad view of the field of aviation during the past twelve months reveals two most important directions in which more than any others, notable progress has been made. These are endurance and stability Particularly in cross-country flying have both the aeroplane and the dirigible established their endurance and reliability. Witness the feat of Brindejonc des Moulinais, who, in exceedingly stormy weather, flew from Paris to Warsaw in 10 hours and 12 minutes, with but two stops, at an average speed of 91 47 miles an hour. Or consider the feat of Stoeffler who, flying to and fro across Germany, as though the whole Empire were but an aerodrome, covered in 24 hours a distance of 1,350 miles at an average speed of 56 miles an hour. Then turn to the Riviera and see Garros taking wing over the Mediterranean for the coast of Africa, with such supreme confidence in his motor that he stripped the pontoons from his hydro-aeroplane, and, with the machine as thus lightened, covered 550 miles or more in a continuous flight of nearly eight hours, landing safely on the African coast. For records of speed we look naturally to the Gordon Bennett cup annual contest Last year the French won it at an average speed of 105 5 miles an hour. This year it was won in France by a Deperdussin, torpedo-body, monoplane, whose 160 horse-power Gnôme motor drove the machine around the course at an average speed of 124 77 miles an hour Far surpassing this, however, was the feat of the Frenchman, Gilbert, who, on the last day of October, won the Pommery cup by flying from Paris to Puertniz, Pomerania, a distance of 650 miles, at an average speed of slightly over 124 miles an hour The height record was won by Perreyon in a 160 horse-power Blériot, who rose above the earth to a height of 19,685 feet, or about three and three fourths miles Von Blaschke carried two passengers with him to a height of 11,740 feet. Passenger-carrying aeroplanes of large capacity are becoming common. The record for size is held by the Sikorsky biplane, which, with 1,358 square feet of surface and 400 horse-power, flew for over an hour with seven passengers and for fifteen minutes with twelve passengers. America gave to aviation the first power-propelled man-carrying aeroplane It contributed also through Curtiss the first practical hydro-aeroplane; and it looks as though to the many triumphs of the flying boat will be added the crowning feat of making the first crossing of the Atlantic A $50,000 prize awaits this accomplishment; and it is possible that the present year will see the inauguration of transatlantic aeroplane flight In spite of many disasters which would have discouraged a less persistent and courageous people, the Germans seem to have unabated confidence in the rigid dirigible The shocking fatalities, twenty-eight in number, which resulted from the total destruction, through explosion, of Germany's latest and finest dirigible, "L. II," have been definitely ascribed to an error which may be easily corrected in future construction. The many disasters are largely offset by the brilliant successes of the dirigible The largest of these had sufficient capacity to cross the Atlantic, and the maximum speed was between 55 and 60 miles an hour. The record of the past year shows that both the aeroplane and the dirigible are destined to find their greatest immediate field of usefulness as an arm both of the military and the naval service, the former for swift reconnaissance for limited periods of time and the latter for more extended observations lasting for many consecutive hours. The sensational feats of Pégoud and others have shown that the aeroplane possesses far greater stability if properly handled than was supposed. To this is to be added the fact that the gyroscope and the swinging pendulum weight have both been utilized successfully for giving to the aeroplane satisfactory automatic stability.

Miscellaneous.

Of the incidents of general interest in the field of science which have taken place within the past year, probably none has attracted such universal attention and feeling as the publication of the history and fate of the Scott Antarctic expedition. We have in due season paid our homage to the heroes who thus perished in the pursuit of science. In the field of anthropology intense discussion has been aroused by the discovery of the Piltdown skull and the divergent con-

(Concluded on page 28.)

The molds travel in endless procession to the pouring point.

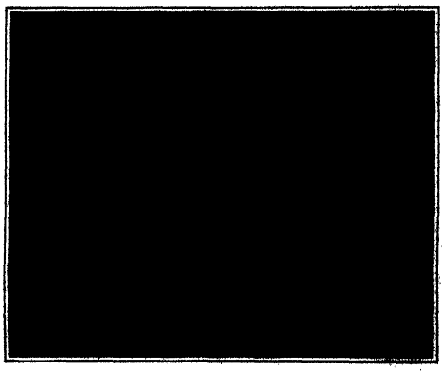
Going Through the Shops—I

The Scientific American's Associate Editor Sees How a Factory Turns Out a Thousand Cars a Day

By A. Russell Bond

YOU may pay five thousand dollars for an automobile or only half a thousand, and, in either case, if your choice has been wise, you will get your full money's worth. Which is to say that widely differing species are classified under the generic term "automobile." The species range from the cars of luxury, models of beauty and power, smooth, quiet running machines, possessed of every latest wrinkle of convenience and whim of design that fashion may dictate, all the way down the list to the humble members at the other extreme, not works of art but of utility, staunch machines, small, but amply powerful for all ordinary purposes and possessed of an amount of "go" that is really astonishing when we consider their exceedingly low cost.

Manifestly, we cannot discuss the manufacture of machines so divergent in one and the same article and, therefore, we shall defer to a later installment the exceedingly interesting processes employed in the building of the more refined product, and take up now the equally interesting story of how the low-priced car is manufactured. Curiously enough, the production of the latter car involves the greater outlay of capital and ingenuity. However, the outlay is manifest not in the machine, but in the plant that builds it. If a motor car is to sell at a low figure, it must necessarily be made in large quantities. Engineers must resort to every mechanical kink and contrivance that will simplify the work and save precious moments.

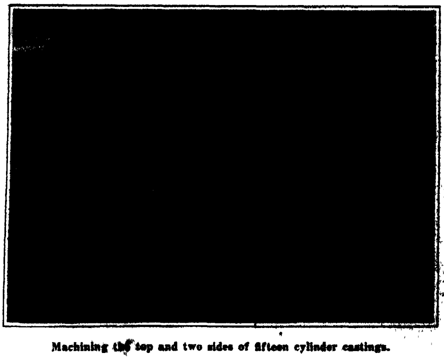


A drill inverted to save time in placing the casting.

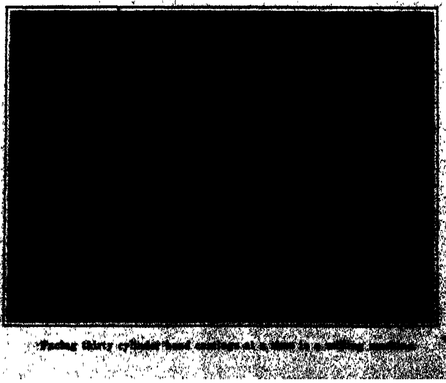
The accompanying photographs will serve to illustrate how system has been carried to an extreme in the manufacture of the small automobile. The pictures were taken in a factory which, during the busy season, turns out a thousand automobiles per day. From the foundry to the assembly department the work has been analyzed to the minutest detail with a view to economizing time. Men are given tasks that are very simple in themselves, and, by dint of repetition day in and day out, acquire a knack that may cut the time of the operation in two. A man may become a specialist in so insignificant an operation, for instance, as putting in a certain bolt in the assembling of the machine.

We have space to illustrate only a few of the apparently infinite stages involved in the building of the car. Starting with the foundry we find a row of cupolas, one of which is always ready to deliver a stream of molten metal. In front of the cupolas overhead is a track of I-beams laid out in a long loop that runs by the molds. Mounted to travel on the lower flanges of the I-beams are carriers from which are suspended large ladles or "shanks" into which the metal is poured. The ladles are then moved along the track until they come to the molds. Here the molten metal is poured into small hand ladles, as required, and with them the molds are filled. In order to have a continuous supply of molds ready to receive the metal, they are mounted on a series of conveyors. Each conveyor consists of an endless chain of carriers similar to those by which the ladles are transported, and running in a loop of overhead track that lies at right angles to the track for the ladles. On the swings suspended from the carriers, the molds are placed. At one end of the loop, the molds are assembled. Thence they progress to the point where they are filled and pass on to the place where they are removed from the conveyor, and replaced by fresh molds.

The resulting castings, after they have had a chance to season for a few days in the open, are carried into the machine shop on an overhead monorail system which is depicted herewith. Each monorail train consists of an operator's car and two hoists capable of lifting two tons each. These trains pass through the factory, constantly transporting the materials over the heads of the workmen and depositing them where required.



Machining the top and two sides of fifteen cylinder castings.



Facing thirty cylinder head castings at a time in a milling machine.

The mono-railroad that carries castings into the machine shop.

Automatic vertical gang lathe for turning down four pistons at once.

This mono-railroad comprises over a mile of track.

In the machine shop let us follow the operations on the cylinder castings as illustrative of the time-saving methods employed. Two of the photographs show how the cylinder castings and the cylinder heads are machined in gangs. Fifteen cylinder heads may be run through the milling machine at a time, having the top and two sides machined at one operation, while in the milling of the cylinder heads, thirty castings may be attached to the table of the miller at once. The castings are all assembled in jigs so that little time is consumed in securing them to the table.

The cylinders are bored out four at a time to within one thirty-second of an inch of their final dimension, after which they are reamed out true to within one one-thousandth of an inch. The cylinders are tested by placing the casting on a standard over an electric light, inserting a plug gage in the bore and noting whether any light passes between the plug and the cylinder walls.

The drilling of bolt holes and the boring of bearings call for the development of special machinery. In one case, namely, that of drilling the main bearing bolt holes in the cylinder casting, the usual operation is inverted; the casting is supported over the drills which feed upward instead of downward. The object of this is to make use of the lower face of the casting as a working base, letting it rest on the drill table, and centering the casting by means of guides which engage the two outer cylinders, thus saving time in securing the work to the machine. There are many such cases in which startling liberties have been taken with the standard machine tool merely to gain a few minutes of valuable time. For instance, there is a toggle press in which the punches move horizontally. Speaking of punch presses, they have even had the audacity to punch holes in iron castings. A malleable iron casting at the forward end of the drive shaft tube has six holes punched in it at a single operation.

In roughing out pistons, a gang-lathe is used which permits four of the castings to be machined at once. Each lathe member completes all the operations on the piston automatically, one tool facing off the head, another chamfering the upper edge, three others cutting the ring grooves, another cutting the relief in the side of the piston, while still another tool finishes the bearing surface of the piston to within a very small fraction of an inch of its final diameter. After the piston has thus been roughed out, it is put on the lathe and a finishing cut brings it to within [illegible] of an inch of the specified diameter.

[illegible]

[illegible] in connection with this car is the manufacture of the magneto. In the particular type employed, sixteen magnets are used which are secured to the flywheel of the motor while sixteen double coils are mounted on the frame. This calls for the winding of 82,000 coils and the manufacture of 16,000 permanent magnets per day. The magnets are cut out of stock to the required size, heat treated, bent to U-shape, heat treated again and straightened. Then they are magnetized by merely touching them to the poles of powerful electro-magnets. After they have been magnetized, they are assembled in trays, as shown in one of the photographs, with the north pole of one magnet touching the south pole of the next adjacent magnet, and so on. The field coils are wound in gangs of eight, insulated copper ribbon being the conductor employed. The winding operation is very simple and, as eight coils are produced at a time, it is possible with three or four hand machines to furnish all the coils required.

The rear axle of the machine is rather interesting. It consists of two tubes, each of which is flared at one end in a bulldozer and fitted over a bell to which it is welded in an electric welder. Two of these axle sections are put together, the bells forming the housing for the differential. The gears are tested by placing them on an arbor connected with an index needle and turning them in mesh with a master-gear, when the slightest eccentricity will be shown greatly magnified by the needle. Before the rear axle may be assembled in the chassis it is put through a test which consists in running the drive shaft with an electric motor in order to work in the gears. If they make too much noise they are simply discarded and go to the scrap heap. Similarly the motor of the car is tested by running it for a time until its bearings have been eased up.

In the machine shop there are so many machines going at once, such an infinite variety of work being performed, that one emerges from it in a daze. In the assembly department, however, the operations are more readily comprehended, and one is fascinated at the miraculous growth of the machine there before his eyes. An assembled rear axle is laid over a pair of horses, the side frames are added, the front axle applied, the wheels mounted, then it moves on to where the engine is fitted in place; another advance and the dashboard and steering gear are bolted fast; at the next step the radiator is affixed; then the gasoline tank is mounted on the chassis and filled with fuel, and almost before we realize it the completed chassis has reached the end of the line.

It is difficult to start a new engine before all the parts have worked themselves into their bearings, and so the machines are not cranked, but are started by pressing one of the rear wheels against a pair of rapidly revolving pulley wheels in the floor. At the same time, a rubber hose is connected to the exhaust pipe of the engine, so that as soon as the motor does start up, the gases will be carried through the hose to the outside of the building. The chug of the motor is heard. A lever is thrown. Off starts the chassis through the doorway, wrenching itself loose from the exhaust hose. In an instant it has disappeared around the corner in a cloud of smoke. The trial spin ended, it re-

Magnetizing magnets by touching them to the poles of powerful electro-magnets.

turns to another point in the plant where a car body comes down an inclined chute from an upper floor and is rapidly clamped to the chassis by specialists in this particular line of work. And lo, a new automobile has been born. But congratulations must be short-lived because another is on the way and due to arrive within less than a minute.

The Car of 1914

As we gaze backward over the stretch of years that commenced with the birth of the automobile, one thing stands out clearly among the mighty improvements that have been made. The six-cylinder car is predominant. From a small beginning it has swept on until in 1914 it has well-nigh carried all before it. It is the prevailing feature of the past automobile year beside which other features pale—but not into insignificance.

The year gone by has seen an unprecedented number of prominent automobile manufacturers proclaim their adherence to "Sixes Exclusively." Others, who, up to the opening of the 1914 season, have looked at the six-cylinder car askance, have been compelled to take it up in self defense. If we delve into figures, it is revealed that the number of makers who produce six-cylinder cars exclusively has increased from an inconspicuous three per cent of a total of twenty-eight well-known makers in 1908 to 34 per cent of forty-two makers in 1914. The figures illuminating the decline of the four-cylinder model are even more impressive. Sixty-four per cent of twenty-eight makers produced four-cylinder cars exclusively in 1908; in 1914, but 12 per cent of forty-two makers will list only four-cylinder models. The percentage of manufacturers producing both four- and six-cylinder models shows equally startling changes. In 1908—only six years ago—one fourth of the twenty-eight makers produced both; in 1914, no less than 54 per cent of forty-two makers will produce both. It is plain that the "six" is the predominating car and that the promise of 1913 in this respect has been more than fulfilled.

It goes without saying that the car of 1914, be it "four" or "six," is a better car—better in a number of respects. But, as was the case last year, the change is largely in details.

Among the more noteworthy features is the manner in which the new season's models have been electrified. In addition to the electric starter and electric illumination we now have the electric gear-shifter and the electrically controlled two-gear drive-axle, both brand new features. That the former bids fair to remain with us is indicated by the fact that not one, but several, well known makers have adopted it, and though there are those who hold to the belief that not more than the mere selection of the gears should be done electrically, leaving the actual shifting to more mechanical means, the opinion is by no means general. The two-gear rear axle would seem to fill a need of the four-cylinder car; for it permits the engine to be operated more nearly at its maximum efficiency under all conditions, and, in a measure, insures that smoothness of action which is a characteristic of the "six" at low speeds.

Electric engine starting and lighting apparatus has advanced, too. The apparatus is lighter now than it has been in the past and therefore is more efficient. There seems to be a tendency toward the utilization of separate units rather than a combined unit for the two functions, although opinion is still largely divided as to which is the better method. At any rate, electric engine starting is now supreme. The demand for it has virtually forced every other type of starter off the market, a fact which is well exemplified by the action of several prominent manufacturers who have used pneumatic starters for years, but who have cast them out for electrical apparatus for their 1914 models. Another feature which is new to the 1914 car is the combination of side and head lamps, a palpable improvement too long deferred.

The silhouette of the 1914 car is changed. In the first place it is slightly lower, which may be expected to affect stability, and there is a marked tendency toward the adoption of the sloping or tapered engine hood so prominent a feature of foreign cars. Between the engine hood and the dash we now have a concave scuttle instead of one that is convexed in a great many cases, and this, with the general tendency toward the carrying of spare tires at the rear of the tonneau, has had a great influence in altering the silhouette of the car. With deeper scuttles has come the dash gasoline tank, which bids fair to supersede the tank hung at the rear. Here again is the silhouette changed.

It is interesting to note—and the conclusion can be drawn from an inspection of almost any of the new models—that American designers at last appear to be paying much deserved attention to the Prince Henry type of stream-line body. Slowly it is being driven home that vehicle efficiency can be increased by the simple expedient of carefully designing body curves so as to take advantage of the entering-wedge principle. Although designers have not carried the idea to its extreme [illegible], the tendency is nevertheless toward a reduction of wind resistance. Body designers would do well to take a leaf out of the aeroplane builders' book in this respect.

Another feature worthy of more than passing note is the unmistakable trend toward the adoption of domed mudguards. Two years ago not more than two or three American cars were fitted with them. Now, however, it is different. Not only do the domed mudguards fit the wheels better—of itself a laudable attempt to enhance appearance—but they act as a surer protection than do the flat ones, and for this reason they must be hailed as a material improvement.

With mention of the general widening of seats and doors, the latter being now for the most part of the full U shape, the clearing of running boards and the almost universal adoption of windshields that are built into place and no longer can be looked upon as accessories, bodies can be dismissed. It is pertinent to add, however, that left side control has materially increased in popularity, a fairly large number of makers who last year clung to right side control, having switched over in response to the insistent demand. One maker who retains right side control has solved the problem by hinging his steering wheel so that it may be folded down out of the way of passengers entering or leaving the front compartment.

With regard to mechanical construction, the influence of the Knight type engine, which appears to be holding its own in public esteem even if it has not made a remarkable gain during the past twelve months, is more than ever apparent in the efforts which have been made to silence poppet valve mechanisms. There is scarcely a maker who does not inclose valve parts by way of muffling such slight noises as cannot be eliminated by more careful fitting and the reduction of clearances to the minimum. The growing use of the so-called silent chain for camshaft and magneto drives is generally credited with reducing the noise of operation considerably.

There is a well defined tendency to reduce the weight of reciprocating parts by way of reducing vibration, and smaller bores with correspondingly higher piston speeds are coming into greater favor; but the stroke to bore ratio gives no indication of increasing.

The year has been marked by the attempts of several makers to equip their cars to use kerosene, and in at least one case results have been so gratifying that the maker feels justified in warranting results with the heavier fuel. At the same time those who cling to gasoline have in many cases made attempts to increase engine efficiency by dash carburetor adjustments, whereby either the supply of fuel or of air or both can be readily adjusted by the driver. Dashes in general carry more equipment than they have in the past. The attempt of a year or so ago to clear away everything off the dash, leaving nothing for the operator to watch, has come to nothing, and dashes now are cluttered up to a greater extent than ever before.

In the mechanical construction of the car, no startling changes have been made. The four-speed gearset holds its own, as does the bevel gear final drive. Contrary to the general belief of a year ago, the worm drive has not made the advance that was promised for it. Instead, makers seem to prefer the perfection of the bevel drive or the adoption of something else, the ingenious combination of bevel and spiral gear that has been placed on all the cars of one maker serving as an excellent case in point. Abroad there has been developed and placed in use by one maker a double herringbone driving gear. Nothing of the kind has as yet appeared in America.

In conclusion we would add that no review of progress would be complete without at least passing mention of the recent development of the miniature automobile which has come to be styled "cyclecar" for the want of a better name. That the present demand for these vehicles is largely an assumed one is the consensus of opinion of automobile engineers, and several of them even deny the permanency of the type, primarily because of its narrow tread and the difficulty of producing it at a price low enough to avoid skimping in construction.

Preserve Your Papers: They Are of Permanent Value

By taking a little trouble, when a paper first comes to hand, it may be preserved to form a permanent and valuable addition to the reading matter with which everyone should be supplied. We furnish a neat and attractive cloth board binder, which will be sent by mail, prepaid, for $1.50. It has good strong covers, on which the name Scientific American or Scientific American Supplement is stamped in gold, and means by which the numbers may be securely held as in a bound book. One binder may thus be made serviceable for several years, and when the successive volumes, as they are completed, are bound in permanent form, the subscriber ultimately finds himself, for a [illegible] to any library, [illegible] life and general [illegible] illustrations, [illegible]

[illegible]

E[illegible] Moore [illegible] and K. L. Kithil, [illegible] vanadium ores, the [illegible] the development of methods for [illegible] raw material into finished products. [illegible] side of the investigation Dr. Moore was assisted by C. F. Whittemore.

As a result of [illegible] recently issued by the Bureau of Mines, it has been definitely shown that, although the Austrian government has conserved its own resources of uranium and radium by purchasing the Joachimsthal mines and by carefully supervising pitchblende production, the deposits of radium-bearing minerals in the United States are being rapidly depleted by wasteful exploitation, chiefly for the benefit of foreign markets.

Seemingly the country has been quite unaware of the extent to which uranium ores have been sent abroad. Investigation has developed the fact that during the year 1912 carnotite ores carrying 28.8 tons of uranium oxide were produced and that practically the entire amount was exported. The major part of this ore carried between 2 and 3 per cent U_3O_8, as it appears that no ore carrying less than 2 per cent can at present prices bear the cost of transportation. This means that 8.8 grammes of radium chloride, or an equivalent 11.43 grammes of radium bromide, will be obtained from the ore shipped from this country in 1912. Only one American company has been preparing radium salts of a high degree of radioactivity, and its product has only recently been offered for sale. The American ores exported were purchased for their radium content. It is improbable that all of the ores exported are now represented by finished product, but the 1912 production of radium from American ores can not have been much less than the quantity mentioned, for uranium was being shipped abroad in almost equal quantities in 1911, and is still being sold for future manufacture. It can probably be definitely stated that in 1912 there was obtained from American ores nearly two and one half times as much radium as from all other sources combined.

In the mining of uranium ore, for every ton marketed there are at present some five tons of low-grade material thrown on the dump and much more left in the mine awaiting only a feasible concentration process for commercial exploitation. Mr. Kithil has shown that elutriation can be applied to both uranium and vanadium ores and that a large proportion of the valuable material now going to waste can be readily obtained in marketable condition. If water is not available, air separators may be used, or other devices for dry separation. The uranium deposits of Colorado and Utah are being rapidly depleted for foreign exploitation, and it would seem to be almost a patriotic duty to develop an industry that will retain our radium.

Although no one can predict with certainty the value of radium or its possible application to science or medicine, the subject is certainly well worthy of investigation by our highest scientific authorities, and under proper technical control, it opens to American industry a profitable field for exploitation.

Although at $90 per milligramme for radium chloride the total value of the radium shipped in 1912 amounts only to $792,000 and the mining and separation of the ore can accordingly be considered only as one of our smaller industries, the fact should be noted that of this amount approximately $716,000 went into foreign hands and opened to foreign medicine and science opportunities in this most promising field that have been denied to our own people, except by repurchasing the manufactured radium compounds at an almost prohibitive price.

France, Austria, England, and Germany have their radium institutes fostered by their governments or by philanthropic foundations. Up to the present time, although the United States has been furnishing a large part of the material for these foreign institutions, comparatively little has been done in the hospitals and laboratories of this country.

A Meteorological Office in Edinburgh.—The British meteorological service, in cooperation with the Scottish Meteorological Society, is planning to establish an office in Edinburgh, [illegible] Office, London, [illegible] information will be [illegible] authorities and the public.

[illegible]

[illegible] was [illegible] the dis- [illegible] with- [illegible] that [illegible] by a [illegible] Navis [illegible] it is safe [illegible] will be more [illegible]

[illegible] is advocated by Dr. Charles A. R. Campbell, who claims to have exterminated countless millions of the malaria-carrying pests by means of a "bat roost" erected alongside a large body of foul, stagnant water near San Antonio, Texas. The roost is a tall wooden structure, not unlike the [illegible] places of [illegible] during the day. It is provided with a tall [illegible] free ingress but [illegible] light. Dr. Campbell finds that mosquitoes are by far the commonest food of bats. Since the roost was erected, in 1911, it is claimed that both mosquitoes and malaria have become scarce in the neighborhood.

Plans for the Proposed College of Tropical Agriculture in Ceylon, mention of which has already been made in these columns, have recently made rapid progress. The college is to occupy 40 acres on the left bank of the Mahaweli River, opposite the Royal Botanic Gardens at Peradeniya, at an elevation of 1,600 feet above sea-level. The main buildings, which will cost $200,000, are to be arranged similarly to those of the Cornell College of Agriculture at Ithaca, N. Y. The lectures will provide for two groups of students; men with degrees in agriculture who wish to specialize in tropical agriculture may take a one-year course, while courses of two years or more will be given to less advanced students.

Sleeping Sickness Investigations.—By way of a postscript to the article on sleeping sickness in the SCIENTIFIC AMERICAN SUPPLEMENT of August 15th, it may be stated that Sir David Bruce, during a recent brief visit to England before resuming his work in Africa, declared that the sleeping sickness in Nyasaland is not the same as that of Uganda or of the West Coast, although it belongs to the same category. It is more rapid and equally fatal, no cases of recovery having been recorded. According to the London Times, the Colonial Secretary has appointed a committee to investigate the whole subject of the spread of trypanosome infection among man and stock by tsetse flies in Africa. It is proposed to try an experiment of game destruction in a localised area, and to consider whether it is advisable to attempt the general extermination of wild animals with a view to checking these appalling diseases.

The International Institute of Agriculture now numbers 53 countries and colonies among its adherents, the latest additions to the list being Paraguay, Guatemala, the Dutch East Indies, the Union of South Africa, Tripolitania, and Cyrenaica. The fourth session of the general assembly of the Institute was held in Rome, May 6th to 12th, under the presidency of Count Francisco Guicciardini. The United States was represented by five delegates. Probably the most important subject of debate was that concerning the promulgation of an international agreement in regard to the control of plant diseases. At present many countries, including the United States, enforce plant quarantines or otherwise contribute to the common task of checking the spread of plant diseases, but many others do not. Although the assembly passed resolutions in favor of the maintenance of government phytopathological services throughout the world, an international service seems still remote. It is hoped that the French government will soon convoke an international meeting of specialists to consider this question. To meet the growing expenses of the Institute, it was decided to increase the subscriptions of the adhering countries; that of the United States will hereafter be [illegible] per annum. The recent publication by the Institute of the [illegible] Year-[illegible] is said to have greatly [illegible] international data, [illegible] the work of [illegible] for its [illegible] connected with the [illegible] languages [illegible] the project is now under consideration of compiling a polyglot vocabulary of the [illegible] terms employed in agriculture. [illegible] affirming the [illegible] of protecting [illegible] its further [illegible] were the [illegible] concerning [illegible] fertilizers.

Automobiles

[illegible] died recently in Paris. He was considered one of those who had done most to advance France to a leading place among the nations in the motor car industry. [illegible] claim to fame, however, is his services in 1908 to Wilbur Wright. Wright found a friend in M. Bollée who placed his services at his disposal and brought about the demonstrations at Le Mans which convinced the French people that heavier-than-air flying machines were an actual possibility. From then on, Wright's success was assured in Europe.

Now Comes the Home Gasoline Still.—On account of the constantly increasing and almost prohibitive cost of gasoline as an automobile fuel, competition has become keen in the production of motors, carbureters, fuel savers and even low grade fuels. However, an English company has designed a small still by means of which an automobile owner may convert four gallons of crude oil into three and a half gallons of fuel in two hours. The oil is placed in the lower part of the still and heated by means of a burner underneath, this burner being operated on gas or oil. The vapor arising from the heated oil is condensed in cooling coils surrounded by cold water, and is drawn off at the side into any suitable tank or vessel.

An Unusual Type of Car Heater.—To utilize some of the heat of the waste products has been the object of quite a number of persons who have sought to increase the comforts of winter motoring; but not all of them have been successful. A new type of heater that but recently has made its appearance has a number of commendable features, first and formost of which is that it may be easily attached by almost anyone who is handy with tools in a short space of time. In its simplest aspect the heater is nothing more than a miniature radiator such as commonly is used for hot air, steam and hot water heating. Part of the exhaust gas is led from the exhaust pipe through the radiator, whence it escapes through a relief vent to the outer air. It is in the manner of admitting the heated exhaust products to the radiator, however, that much of the novelty exists. Instead of a plain valve in the exhaust pipe there is a rotor, operated by the pressure of the exhaust gas, which in turn opens a small disk valve that admits part of the products of combustion to the radiator; thus only a small part of the gases pass into the radiator, the exact amount being governed by a small lever which in turn is connected to the disk valve so that the opening may be varied. As the heating surface is large and the tubing is fairly light only a comparatively short time need elapse before the heat is felt by the occupant of the car. To attach the device it is merely necessary to section out a small piece of the exhaust pipe and substitute for it the combined rotor and valve that go with the heater. In the construction, two heaters are used, one in the front and one in the rear of the car, though only one need be used and it can be placed wherever the fancy of the owner dictates.

A Semi-solid Pneumatic Tire.—A new tire has made its appearance, which is a sort of combination of solid and pneumatic. It is not unlike the ordinary tire for which it can be substituted without alteration in existing standard tire-rims. Its principal point of difference lies in its enormously thickened tread and in the unusual manner in which the tread is formed. The tread itself is four or five times as thick as the normal tread and formed in it there are a number of very deep indentations alternating on either side and overlapping slightly at the center of the tread. Between these indentations, at the sides there are other scooped out places, the purpose of which is to assist in the radiation of natural heat. By means of the deep indentations it is pointed out that the principal drawback to the solid tire, barring its lack of resiliency, of course, is eliminated. This drawback it may be explained is due to the fact that the weight of the car and its progression force a ridge, or wave, of rubber around the tire just in front of the point of contact between the tire and the road, the net result being that the tread soon loosens itself from the base and comes away. The indentations, it is claimed, do away with the travel of this wave by permitting distortion to take place and allowing for the return of the rubber to its natural form. Incidentally, their edges provide a means for the tire to bite its way through mud or water and [illegible] an acquaintance with the roadway itself. Consequently the tire is practically nonskidding. The thickness of the tread obviously accounts for the fact that the tire is more than ordinarily resistant to punctures and blow-outs and so confident are the makers that the tire will not only stand up in service but will stand up an unusually long time to boot that they unreservedly guarantee it for 5,000 miles, 1,500 more than the manufacturer of ordinary tires. Despite the heavier tread of the tire, which is used with the ordinary inner tube, its weight averages only about 10 per cent more than the weight of the ordinary tire.

Centrifugal Force on Automobile Tires

By C. E. Palmer

AT first glance it would seem that each and every element going to make up the running gear of the modern automobile is balanced to such a nicety that any speed attainable under normal conditions would hardly be sufficient to necessitate serious consideration being given to any small, unbalanced weight. However, it has been demonstrated that even such a small weight as the tire valve is subjected to sufficient centrifugal force at high speeds, especially in racing cars, to warrant the placing of an equal weight on the opposite side of the wheel to overcome the energy developed by the rapid motion of the unbalanced valve.

The valves, including their caps, vary in weight for the different sized cars on which they are used, from 3½ to 8½ ounces, and these weights seem insignificant when compared with the weight of a wheel and rim. But when the wheel is revolved at several hundred revolutions per minute a considerable centrifugal force is exerted, acting at any point in its travel radially away from the center of the wheel. It is intended to show here the tremendous forces that are developed at different speeds if the valves are not counterbalanced by weights on the opposite sides of the wheels.

The velocity in feet per second of any particle of matter moving in a circular path with a constant radius, is represented by the product of the circumference and the number of revolutions per second. Now the centrifugal force of the same particle is the product of the weight and the square of the velocity, divided by the product of the radius and the force of gravity, which is 32.16 feet per second. Then substituting the value of V^2 in this second formula, we derive the equation, $C = 0.00034\ W\ R\ N^2$ pounds, where W is the weight of the body, R the radius of action, and N the revolutions per minute.

For the purpose of demonstrating by means of this formula, the necessity of balancing the wheels on high speed cars, values will be assumed to correspond as nearly as possible to actual practice. Let the distance from the center of the wheel to the center of gravity of the valve, be 15 inches; the weight of the valve and cap, 7½ ounces or 0.468 pounds; and the diameter of the tire, 36 inches. Cars which will not attain a speed of 60 miles per hour are unusual, and it is an every day occurrence for racers to maintain a speed of 75 or 80 miles per hour throughout a long contest or trial run. As a speed that is not at all unusual, let us assume 70 miles per hour for the first example. This is equivalent to 6,160 feet per minute, and in traveling at this speed a wheel with a 36-inch tire will make 654 revolutions per minute. Substituting these values in the above equation we get:

$$C = 0.00034 \times 0.468 \times 1.25 \times 654 \times 654 = 85.1 \text{ lbs.}$$

In other words a 7½-ounce valve on a 36-inch wheel traveling at 70 miles per hour will exert a lifting force of over 85 pounds when the valve reaches the top of the wheel. In case both valves of either pair of wheels are in the same relative position with regard to the axle, they will exert a combined lifting force of 170.2 pounds, and if they are opposite each other there will be a seesawing force acting on the car. Considering that there are four of these valves it is easily seen that they will exert forces in various and constantly changing directions as the wheels shift their relative positions in rounding turns in the road.

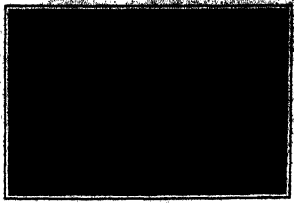
Since the centrifugal force varies as the square of the speed it requires only a slight increase in the speed to make a large increase in the force exerted. For instance, if the car travels at 75 miles per hour the force is increased to 97.5 pounds, and at 80 miles, which is frequently attained, the force on each valve will be 111.3 pounds, while at only 40 miles the force is 28 pounds. In a car going at the fastest rate of speed yet attained by man, 142 miles per hour, the force exerted by the valve is nearly 400 pounds.

Considering these almost neglected forces it is easily seen that some cognizance of them should be taken the same as is done is designing balanced wheels of stationary machinery. That racing drivers are coming to realize what these neglected forces might mean in case of an accident and loss of control of the car, is shown by the fact that a famous English driver has equipped each of his tires with two valves instead of one, the valves being placed on opposite sides of the tires in order to provide a perfect balance. It is said that the car will run at 80 miles per hour and hold the road remarkably well, where before it skidded badly at high speeds and was very difficult to control. Many American drivers also balance their valves by placing metal weights on the rim or felloes of the wheels opposite the valves.

Elk in Utah.—Elk have been found in the Uinta national forest, Utah, for the first time in many years. Since they are not from shipments from the Jackson Hole country to neighboring forests, the State and Federal officials are gratified at this apparent increase in big game as the result of protection.

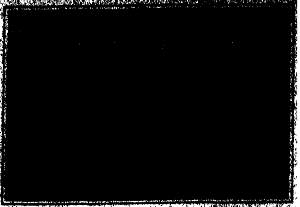
An interesting example of the "boat type" body.

The peculiar feature of the design lies in its ram-like forward lines and its torpedo stern; it is styled a skiff-torpedo and the body, though metal, is grained to represent wood. Lightness of construction evidently was sought, for running boards are missing and the mudguards are small.



Modified type of two-passenger coupé model.

When closed, this body has much the appearance of a "conning tower." It is a good example of the European practice of sloping the engine hood sharply to blend with the lines of the deep scuttle. Owing to the lowness of the chassis, the body appears somewhat squat when the back is folded up.

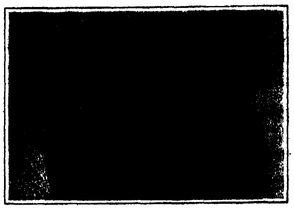


A clever solution of the seating problem.

In this body, the designer has placed the [illegible] seats en echelon by way of giving all three occupants plenty of elbow room. The design, incidentally, provides for sociability among the passengers; conversation is facilitated, for no one is required to lean over any one else.

Ingenious storage spaces that satisfy a real demand.

To provide for the safe carrying of goggles, gloves and the hundred and one other motoring necessities is not always easy, though the designer of this body has not found it particularly difficult. In the average American car, storage space of the kind is unknown.

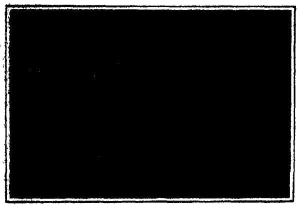


Is closer resemblance to a real boat possible?

The fidelity with which the boat builder's art has been imitated in this body is truly astonishing; the "hull" is properly built up of a number of "skins;" decks are laid in true nautical fashion and even the cockpit has a coaming. Note the protected fuel tank.

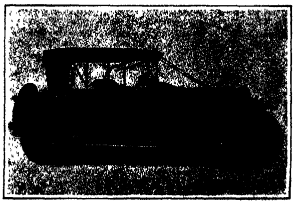
Dodging the conventional in front elevations.

The resemblance to an aeroplane with its widespread wings is unmistakable. The miniature "side" lamps, set into the dash, are in marked contrast to the powerful head lamps. The windshield, unbound at the top, reflects a well-defined tendency in design. The body is styled a skiff-torpedo.



Side view of lately developed runabout model.

Compactness is the predominating feature of this vehicle which somewhat resembles a great black beetle, what with its sloping front and rear and its low-hung chassis. The provision of ventilators on the rear luggage compartment is unusual.



American three-passenger car that is different.

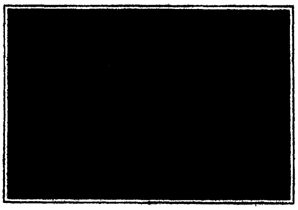
The third seat at the rear closes up out of sight and when closed is waterproof; besides it there are commodious lockers. The position of the tool box is worthy of note, for though fairly large, it does not obstruct the running board

Clever combination of sedan and limousine.

When the top is folded back, as shown, the body is to all intents and purposes an open touring body; but when it is raised the occupants may be as snug as the proverbial bug. What a contrast between the curving fender line and the severity of American practice!

Another of the curious foreign "boat" bodies.

The exaggerated flare to the top-sides, the tiny after cockpit and the peculiar stern all proclaim the marine origin of the type. Mudguards are reduced to the minimum, it will be noted, and there are no side entrances to the single rear seat; running lamps are mounted atop the head lamps.



How foreign designers reduce wind resistance.

Type of racing body in which the stream-line principle is well exemplified, the theory being that the pressure at the rear nearly neutralizes the head resistance. The extreme to which the idea is carried is indicated by the rudder-like projections on the rear frame members.

Another view showing lines of the "terra marine" body

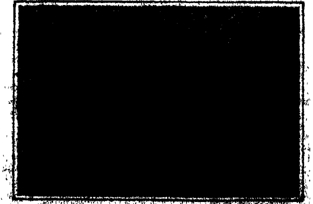
From the side, the resemblance to a boat is even more pronounced; the lines are those of the typical, fast runabout launch. The illusion is made complete by holding a card so as to obscure the engine hood. This body caused a genuine sensation at the recent French salon.

A representative type of fast foreign runabout.

Disked wheels, practically unknown in America, serve to reduce wind resistance and to promote cleanliness; they are fairly common abroad where little attention is paid to convention in the matter of appearance Note the "turtle-back" rear effect and the lowness of the chassis.

The exaggerated coupé type of town vehicle.

The apparent great length of the chassis is accounted for by the fact that more than half the space is taken up by engine and driver. The abrupt, unfinished appearance of the inclosed part offsets the elaborate attempt at line blending at the front.



Brand new arrangement of seats and storage space.

It will be noted that the forward seats are [illegible] for the [illegible] purpose of providing both [illegible] of room, and half the tonneau is [illegible]. The body is a utilitarian one, though the [illegible] is somewhat limited.

NEW IDEAS IN CAR BODIES DEVELOPED CHIEFLY ABROAD

The Adaptability of the Motor Truck

Installations That Fail Because the Trucks Are Not Worked to Their Full Capacity

By W. A. McDermid

As a piece of labor-saving machinery, with a very wide range of designs and sizes, it is obvious that the motor truck should be selected with a view to its exact fitness for the character of the work. This is, in fact, so obvious that too much emphasis has been placed upon it, and it has been made the prime consideration in the operation of motor vehicles, with the result that through the neglect of other and more important factors, the truck has had to bear the blame for failures to produce the economies of operation of which it is really capable.

The evidence which demonstrates the advantages of motor truck transportation is so overwhelming that it is difficult to understand why there should be in many cases a serious question as to the real value of the truck. Yet far-seeing truck makers, their salesmen, and thoughtful business men who are considering this investment are frankly facing this situation and seeking to determine the reasons back of this condition in the motor truck industry.

It is apparent to them that there are hundreds of very successful motor installations where a large economy in dollars and cents is clearly traceable. There are many others in which a premium—an additional cost—is gladly being paid because of certain superior facilities or services which the motor truck affords, and which are considered worth the price and therefore a profitable investment. And there is a third class, in which the cost of operation has been so prohibitively high, as to render the purchase of trucks an apparently mistaken investment.

Part of this last situation has been due, no doubt, to the over-enthusiasm of the truck salesman, who, in perhaps an excusable zeal for his product, has led the prospect to expect the impossible, or has failed to analyze the customer's needs, or, having analyzed them, has not been sufficiently frank to admit the inadequacy of his particular make for the purpose.

While the manufacturers themselves realize this tendency and for the most part combat it vigorously, this is not, however, by any means the root of the trouble. There are instances beyond number in which the customer has been clearly and honestly forewarned of what he must do to get efficient results, only to utterly ignore or disbelieve the warnings. The problem lies deeper than this, quite apart from the fact that even if the truck does not live up to the most sanguine statements of the salesman, it should still (under normal conditions) give a more than satisfactory efficiency.

Nor is it primarily due to the fact that the wrong truck has been purchased for a given class of service. Certainly there have been a very great number of mistakes of that kind—mistakes which every man, in whatever capacity, who has the interests of the industry at heart, whether as user or maker, deplores and earnestly seeks to prevent.

Regrettable as such purchases are, it is nevertheless true that even where the truck is perfectly adapted, in style, size and equipment, to the required class of work, there is, in a large number of instances, a heavy loss in economy. It is in seeking to arrive at the underlying cause for this loss that we reach a basic solution of many of the problems of motor transportation.

It is the natural and logical reasoning of the salesman and the purchaser that if the truck itself is well designed and made (and in the present state of the industry there is an ample choice of such trucks); if it is the suitable type for the work in hand, and if it is placed in the hands of a competent man, it should prove to be an unqualified success. This reasoning, however, is not justified by experience.

An analysis, based on accurate time studies and investigations of operating conditions, of more than two hundred average motor delivery services, in twenty-eight cities, and in forty-two lines of business, each with unique problems, reveals as a generalization that the average motor truck is from *twenty-five to fifty or even sixty per cent below normal efficiency.*

A very small percentage of this is due to defects in the machines themselves. When repair bills or maintenance expenses are unduly high, they are not traceable, except in a few cases, to bad design or construction, but to careless use.

And the cases of error in selection of the type of truck, while considerably greater in number, still do not represent the major part of the problem. In fact, the most common error of this class, the use of too heavy a type for parcel service on short runs, is due primarily to a scarcity of suitable parcel-car types. In the heavier trucks it is apparent that because of the wide variations in weights and sizes of load units, some inconsistencies are inevitable, and the truck makers have provided for this by a reasonable factor of safety in construction.

The conclusion is, then, that the truck is not properly used by the purchaser in a large number of instances; a fact which has been blamed to the driver, the repair man, the garage superintendent—to every one, in fact, except the real source of responsibility—the management.

The adaptability of the motor truck to its work, barring certain minor considerations, resolves itself into the question as to the amount of intelligent effort the management is willing to expend on it.

There is no other way to account for such a comparison as Figs. 1 and 2. These represent total hours in service and the relation of working hours to idle hours, *of a motor truck selected at random from the fleets of two companies situated near each other in a large city, with the same kind of tonnage, and the same make of truck.* The comparison is as fair as could be made. Both drivers are above the average in ability and intelligence. Truck 1 is not profitable. Truck 2 is paying good dividends, in service fewer hours, and handling greater tonnage.

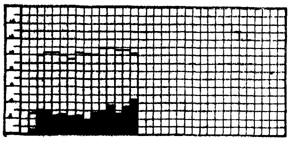


Fig. 1.—Relation of working to idle hours of a motor truck.

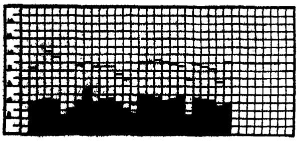

Fig. 2.—Diagram of a profitable truck engaged in the same work as Fig. 1.

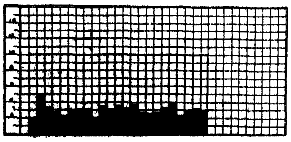

Fig. 3.—A thirty-day analysis of an unprofitable truck.

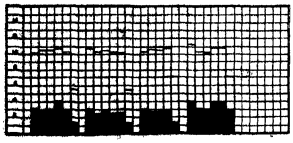

Fig. 4.—Same truck as in Fig. 3 after the management had investigated the delivery service.

Figs. 3 and 4 are the graphic presentation of a thirty-day analysis of similarly parallel conditions in another industry in a smaller city, before the attention of the management was directed to the delivery service in anything more than the usual perfunctory way. After analyzing tonnage, trips, necessary loading and unloading time, etc., it was apparent that increases in efficiency to average 28 per cent in productive working hours were possible, and within ninety days practically all of this increase was effected.

These will serve as illustrations of the principle underlying the economical administration of motor trucks, namely, the importance of the productive working hour. The generalization that a truck must be kept busy is currently accepted and preached broadcast, but there is an appalling amount of misinformation as to how much work the truck in question is actually performing.

Men who are conscientious in the belief that their trucks are rushed to capacity, and who are contemplating the purchase of additional vehicles, are utterly amazed to be confronted by indisputable evidence that their trucks stand idle as high as 60 or 70 per cent of the working day. In fact, those percentages might almost serve as an average.

Many of the secondary ills of the motor truck are traceable to that condition. Bad planning on the part of the management (or lack of accurate information) forces the shipping clerk to overload on each trip to get out the goods—a necessity which extra trips, in a well planned day, would eliminate. The driver is compelled to overspeed to meet the pressure. The result is high repair bills and bad service. The most common and serious mistake is in attempting to cure these symptoms instead of getting down to first causes and considering the motor truck as it should be considered—a unit of productive machinery.

Hundreds of owners are spending large amounts of money and time in keeping elaborate records of costs, and investigating cases of trouble, without recognizing that the same principles of planning and management that apply to the machines in their factories apply in *the same degree to their motor trucks.*

When a truck has been considered with respect to the weight and size of load units for delivery, the territory to be covered, and whether the load is for distribution or delivery at destination as a unit, and has been selected to conform to the conditions, the owner is still far from receiving satisfactory service unless he applies to it the basic theory of manufacturing efficiency—*the largest number of productive minutes of time per unit of machinery.*

Failure to apply this standard is accountable for the fact that there are relatively few fleets that do not contain more units than are necessary for the work in hand.

To take a concrete illustration, a large wholesale grocery company, operating four large trucks (three different makes) found their cost far above that of horse delivery. A time study showed that these trucks averaged barely three productive working hours a day, and the fault was shown to lie in shipping room congestion. The trucks were in no way at fault—they were giving splendid service. But to restore the delivery department to its old costs, or decrease them, it was necessary to improve shipping facilities or go back to horse trucking. By electing the former method, this company is getting the benefits of truck service at a normal cost.

By way of contrast is the concern which operates four trucks which were shown to average but two hours and twenty-five minutes a day of *running time*, yet who ignored the point and purchased two more trucks, when three trucks in all would amply care for the work under proper supervision.

Cases like these illustrations are not the exception. On the contrary, they are so frequent as to be a serious menace to the success of the motor truck. They are changing the motor truck from a powerful servant of society, cheap and efficient, to a costly and wasteful addition to the machinery of distribution.

And the process will continue until the owner learns to discard the standards of horse delivery and apply the principles of engineering to his equipment, and until the maker recognizes that it is not sufficient that he sell trucks to those who will buy, but that he must sell them where they *are really needed, and only then.*

As standards for the successful operation of motor trucks, it is logical to adopt the same principles of production engineering that apply to the lathe, the automatic screw machine, or any other piece of productive machinery. These may be summarized as follows:

1. The machine must be of exactly the right type for the particular class of work it is turning out.
2. No unit must be added, until each preceding unit is working to its capacity.
3. The raw materials of manufacture must be accessible with least possible expenditure of effort and time.
4. The finished product must be promptly removed.
5. The operator must be skilled in the use of the machine.
6. The machine must be subject to the frequent inspection of a competent mechanic. "A bolt in time saves breakdowns."

Good Lubrication—The Motor Conserver

Motor Oil in a New Light

By Harry Tipper

One thing which distinguishes the efforts of men in any direction from the accomplishments of nature, is the small amount of useful work secured by man in proportion to the amount of energy which goes to waste compared with the absence of waste in nature and the complete conversion of all energy into useful work of some kind. The actual amount of power turned into useful work in an automobile compared with the amount of energy represented in the fuel, is only a fraction of the theoretical possibility; neither is the length of life of the parts of an automobile anything but a fraction of what it should be.

Friction—that is, the resistance to movement of one part in contact with another—is one of the largest contributing causes to loss of power and deterioration, and as a consequence of this the effect of lubrication upon the wear and tear, the ability of the motor to withstand strain, and the power delivered, is of the utmost importance and can hardly be over-estimated. Even the spring which supports the body will remain in service infinitely longer if a little care is bestowed on the lubrication between the leaves, so that the movement of one leaf upon the other will be unrestricted and without undue strain upon the metal.

The efficiency of lubrication in any motor driven vehicle depends only to a certain extent upon the character of the oil, other factors exercising a considerable influence upon the results which are obtained. The design of the motor, the design of the lubricating system, the care bestowed upon the running of this system, the character of the oil itself, the care bestowed upon it in refining and distributing, all exercise an influence upon the lubrication and its value as a conservation measure. In this article, written by a well known expert, the importance of good lubrication in automobile operation is considered from a new angle.—Editor.

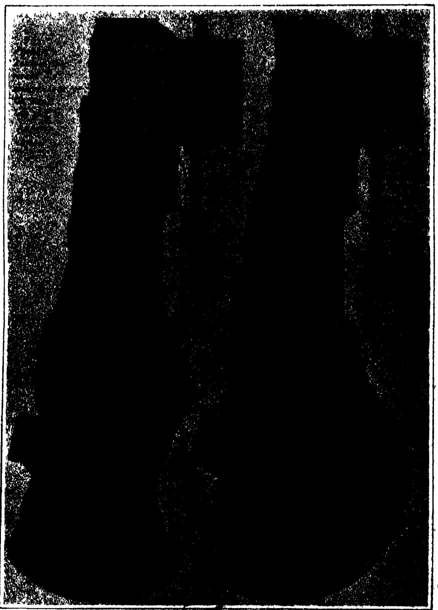
CONSERVATION measures are always the least understood and the last to be investigated. It is, therefore, to be expected that comparatively little study should have been given to the question of lubrication except in the oil business, and only a partial study has been given to it even in that business. Primarily because the study of lubrication in the oil business has been from the standpoint of determining the best way to market certain oils and not always from the standpoint of arriving at the most efficient means of lubricating. This is, of course, to be expected. It does not, however, excuse the engineer who is interested in motor lubrication from the criticism which the neglect of this important subject rightly subjects him to. Little, if any, attention has been paid by the automobile engineer (until the last two years) to the factors which enter into and affect the efficiency of lubrication, and where these factors have been taken into account by the oil manufacturer they have been considered only as exercising a controlling influence upon the character of the oil required. Whereas, it is entirely probable that the character of the oil adapted to the work is not materially affected by the changes in the design of the motor, the lubricating system or other conditions, but rather these conditions have an effect upon the final efficiency of any lubricating oil which is used.

Moreover, where attempts have been made to scientifically consider the character of the oil necessary for efficient lubrication, the conclusions reached and the deductions made from such consideration generally show either a partial knowledge of the conditions in the oil business and the requirements of the motor, or a neglect of some of the factors entering into the case. It is not many years ago that gasoline of high gravity was considered necessary to secure any power, although now it is generally understood that a lower gravity gasoline means greater power and more mileage per gallon and that gravity may change in the gasoline produced from different crudes without affecting the starting value or volatility of the product. These later developments have shown definitely that the characteristics by which the general public (and even the trained engineer) have been used to measure gasoline have little, if any, bearing upon its value as a motor fuel.

Physical Tests Are Not Always Final.

It is now understood by some oil experts (who have conducted their researches very carefully into the conditions in a number of oil fields and conditions in the motor business) that some of the physical characteristics of lubricating oil which are generally quoted as being synonymous with good lubrication, have little to do with the mechanical efficiency of the lubricating oil under working conditions. In this respect oil values are much like creeds and political traditions, the old habits of expression remain long after the deficiencies are known.

Many years ago, when the crude oil all came from the same part of the country and possessed practically the same characteristics, chemical composition, etc., it was a comparatively easy matter to determine whether a uniform oil of uniform value was being secured. Consequently, the crude oil from which the lubricants were taken at that time passed into the standard, and the general physical characteristics were used as expressing the standard of requirement. Later discoveries in oil fields have shown that, like all natural products, oil varies in its chemical and physical characteristics, according to the deposit, and these varying deposits cannot be measured solely by the values established by the characteristics of one field. On account, therefore, of the absence of any valuable standard of comparison in the oil business, and the conflicting opinions which have developed in the study of motor lubrication, the only way to properly consider this subject is to ask what the requirements are and see what qualities are necessary to fulfill them.



If the seal between the piston rings and cylinder walls is good, the mixture will be compressed to a high degree. In order to maintain good compression in the cylinder, an oil must evidently be used which will adhere to the cylinder walls, filling the space between the piston rings and the cylinder walls. If there is a slight leakage on each compression stroke, gasoline may seep into the crank case, making the oil absolutely unfit for further use

The effect of good and bad lubrication in an automobile engine.

How Lubrication Affects Compression.

Inasmuch as most of the obvious trouble in connection with the lubrication of motor driven vehicles comes from the motor cylinders, this point should be considered first. The performance of the motor of any gasoline driven vehicle depends upon the maintenance of the compression, and the efficiency of the motor depends to a considerable degree upon keeping this at maximum point.

It is obvious, upon consideration, that it is practically impossible to fit the moving piston into the cylinder so closely as to secure a high compression without increasing the resistance or friction to such a point that it will absorb a considerable amount of power in turning over the motor without doing any useful work. During the suction or admission stroke, the admission valve is so arranged that it will not admit air into the cylinder as fast as the piston displaces it. This results in creating a partial vacuum which carries the gasoline and air mixture through the carbureter. This partial vacuum will at the same time carry the lubricating oil up past the piston rings into the compression chamber unless this oil is sufficiently tenacious to adhere to the cylinder walls.

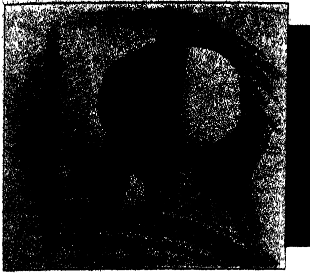
The amount of lubricating oil which passes the rings and gets into the explosion chamber during the stroke is greater or less according to the fit of the piston rings in the cylinder and to the character of the lubricating oil. These same conditions—that is, the fit of the piston rings and the character of the lubricating oil—affect the compression, which can be secured and maintained during the next stroke. The compression which occurs during the next stroke is caused by the movement of the piston upward in the cylinder and this compression depends largely upon the close fit between the piston rings and the cylinder walls; upon the number of rings; and upon the way in which the oil will form a seal between the cylinder walls and the piston rings. When the cylinder is closed, the only loss of compression comes through the fit of the valves, poor mechanical fit of the piston rings or poor and faulty lubrication.

The lubricating oil may be indirectly the cause of poor mechanical fit of the valves and piston or rings on account of hard carbon being deposited thereon. Poor lubrication, even with a good oil, will result in a loss of compression without regard to the perfect mechanical fit of the piston rings. With good lubrication and an oil of the right character, the compression can be maintained even with worn-out rings and a loose piston.

On the next stroke, the explosion of the mixture and the consequent expansion of the gases therefrom produces the power to drive the motor. Provided the carbureter is properly adjusted so that the mixture is in the right proportion for effective work, the amount of power developed from the explosion is largely dependent upon the compression secured during the second stroke; the greater the compression secured during that stroke the greater will be the initial pressure at the time of explosion, and consequently the greater the force of explosion.

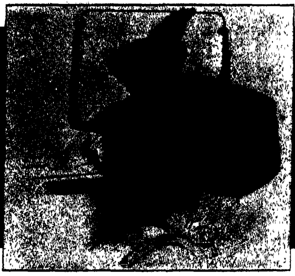
If the seal between the piston rings and cylinder walls is maintained perfectly, the mixture during the second stroke will be compressed to a high degree. At the same time, during the explosion or power stroke none of the force (which should be expended in driving the piston down) will be lost through leakage past the piston rings. Of the power developed by the motor, the percentage which can be used to drive the motor forward, is dependent not only upon the degree of compression, but also upon the way the compression is secured. In other words, in order to turn the power developed by the explosion and the expansion of the gas into useful work, it is

(Concluded on page 34.)



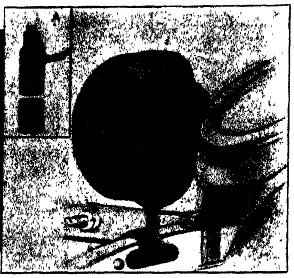
Lamp that illuminates roads without blinding others.

It has been one of the problems of those who design automobile headlamps to provide for proper illumination without blinding those who approach the lamps. In this design the solution has been attempted by showing the brightest part of the light against a light background instead of against the usual dark one. The front domes are ground glass with a small central clear portion.



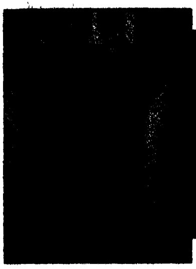
An adjustable windshield for tonneau passengers.

Few automobiles, if any, are sold without a windshield for the driver's protection, yet none are provided with a similar device for the protection of those who ride in the tonneau. This shield has been designed for the purpose. It is light and easily fitted to any body and can be adjusted to occupy a variety of positions. When not in use it is removed, taken apart and packed into a small case.



Emergency burner to make electric lamps burn gas.

We have had devices which transform gas and oil lamps into electric ones and now comes the device which makes an electric lamp into a gas lamp. It is for emergency use, of course, and manifestly cannot be used in the ordinary type of parabolic reflector lamp. The pillar is made to fit the usual electric light socket and can be quickly substituted for an electric light.

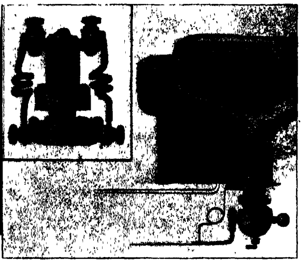


Heater built like a miner's lamp.

It is not a stove, however. Warm air is discharged at the top, but the sides do not get hot. It burns gas and is so arranged that hot air is kept in circulation, though the vent is outside the building. The makers say it cannot cause explosions.

Top that can be raised or lowered by one person without assistance.

The job of raising and lowering automobile tops always has been a difficult one. Usually it requires the undivided attention of at least two persons. With this design, however, one person can not only raise or lower the top without help, but, it is claimed, can do either with two fingers in about ten seconds. It is worthy of note that a great many automobile makers are equipping their cars with tops of this kind for the coming season, the movement, in fact being one of the revelations of the new models. The new top is supported only at the rear.

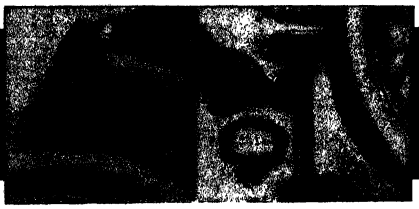


Electric device that helps the engine start itself.

We all know how hard it is to start a cold motor on a cold morning; not even the electric engine starter finds it an altogether easy job. So this device has been developed to assist in starting the engine. It is an electric heater operated from a storage battery. Pressure on a button permits a small quantity of fuel to pass over a heating coil which vaporizes it and fills the manifold with hot "mixture."

Providing automatic spring lubrication.

It is gradually coming to be realised that the leaves of springs require continuous lubrication to avoid squeaks and hard riding. The maker of this spring has overcome the difficulty by forming small grease receptacles near the end of each leaf. They are filled with hard graphite grease every six months, and the movement of the leaves one on the other serves to distribute the grease and provide proper lubrication.

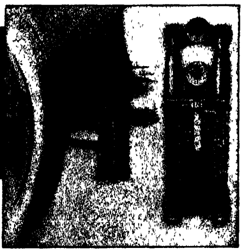


Signal appeals to two senses at once.

It is said that even the deaf take note of this combined bell and signal lamp! The lamp is in series with the bell, and when a button is pressed current from a battery rings the bell and flashes a red or green signal to draw the attention of pedestrians. Obviously it serves its most useful purpose at night. To satisfy the nautical mind, two signals can be used, red for left and green for right, with separate controls.

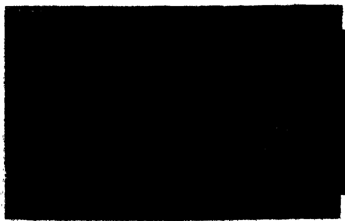
Jacking up the car by foot power.

Nearly every one knows how hard it is to operate a jack by hand under a rear gasoline tank, for instance; the foot is much handier for the purpose, so to speak. This is a stirrup which fits onto the handle of any jack so that the operator can insert his toe into it and hoist the car with his powerful leg muscles—and keep his clothes clean. For really heavy vehicles, strong biceps are needed when the jack is hand-operated.



To smooth out little bumps in the road.

The light springs preserve the chassis from the little jolts not absorbed by the regular vehicle springs, and at the same time act to reduce their natural period of oscillation. The large spring chamber is filled with oil which lubricates the parts and also prevents too rapid motion, thus giving a shock absorbing effect. The device takes the place of the common variety of spring shackle.

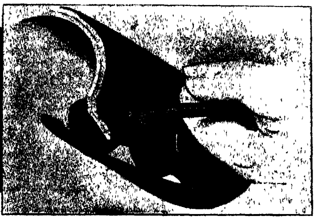


Novel type of "trouble" lamp that stays where it is put.

Magnetism is what makes it "stay put," which means, of course, that it must be "put" on either iron or steel. As the powerful magnet that holds the lamp is in multiple with the four-candle-power bulb, the outfit does not take much current; four dry cells are sufficient. Though designed primarily for the motorist it is a handy thing to keep about the shop. Needless to add, it will stick in any position, upside down or otherwise, and as the magnet exerts a pull of thirteen pounds it is not easily shaken loose.

New idea in mechanical horn construction.

The old-fashioned bulb horn does not emit a note sufficiently abrupt and compelling; its tone is too mild to be heard above the roar of traffic. This horn is one of the simplest that has been devised to take its place. Twirling the handle sets in motion a series of gears, thus causing a steel wheel to rub over a button on the diaphragm.



An ingenious puncture repair outfit with a new plug.

The outfit consists of a tool to insert the plug in punctures and the plug itself which differs from all others in that the stem is flat and the head round. Small punctures are made into tiny slits with a knife, after which the plug is inserted with the tool which first pushes the plug through the slit, then turns it and withdraws the stem. The tube being larger than the slit, and elongated when inserted, expands when in place and fills the hole.

NEW IDEAS IN AUTOMOBILE ACCESSORIES

The Heavens in January

Some Notes on the Planets and Their Satellites

By Henry Norris Russell, Ph.D.

THE comets whose discovery and motions have occupied so much of our space of late are now all well on their way outward from the Sun, and with one exception, are no longer visible in small instruments. Westphal's comet alone remains in the northern sky—its computed position being right ascension 21 hours 25 minutes, declination 57 degrees 50 minutes north on December 31st and 22 hours 10 minutes, 64 degrees 44 minutes on January 12th. It is now about 125 million miles from the Sun and one hundred million from the Earth, and, theoretically, should be about one third as bright as in November, and should fade away slowly. But the actual brightness of a comet is a capricious thing, for, unlike a planet, it shines by its own light. It is certain that the comet is stirred up to shine in some way by the action of the Sun's radiation upon it; but the nature of this action is not yet well understood, and the brightness, and even the apparent size and shape of a comet, often vary greatly in a short time.

Westphal's comet has given a good example of this. In October it was conspicuous in a small telescope. Early in November, however, as Prof Barnard described it, "it simply went to pieces," becoming a faint, vague, elongated mass of feeble light some two minutes of arc in diameter, and since then it has been faint. There is no longer any chance of its becoming visible to the naked eye at this return, but unless it continues to grow unaccountably fainter, it should be telescopically visible for some time to come.

The principal interest this month shifts to the planets Mars and Saturn, which are splendidly placed for observation in the evening sky. Saturn is in Taurus, about 8 degrees northeast of Aldebaran at the beginning of the year, and moves about 1⅓ degree westward during January Mars is farther west, in Gemini, not far from Castor and Pollux, and moves some 8 degrees westward during the month.

Both planets are very conspicuous, Saturn shining with a yellow light and appearing a little brighter than Capella, which is, next to Sirius, the brightest star now in sight. Mars is almost equal to Sirius in apparent brightness, and may be recognized at once by his fiery red color.

Saturn is a month past opposition, and is already well up by nightfall. Mars is in opposition on January 5th, and is visible all night long. He is then almost 27 degrees north of the celestial equator, and hence he soon rises high in the sky, and is well observable in the early evening.

Both planets are splendid telescopic objects. Saturn's rings are opened out at their widest, extending beyond the poles of the planet on the north and south. It is on this account that he appears so bright. Seven years ago, when the rings were edgewise toward us, and we received light from the planet's ball alone, he appeared to the eye only half as bright as now

His largest satellite, Titan, which is easily visible with a three-inch telescope, can be found north of the planet on the 4th, west of it on the 8th and so on, its period of revolution being 16 days. When north or south of Saturn its apparent distance from him is twice the extreme length of the rings, and when east or west of him, four and one half times the length of the rings. The satellite's orbit is really almost circular; but since its plane (which coincides with that of the rings) makes an angle of 26 degrees with our line of sight, it appears foreshortened into an ellipse of the same shape as the rings themselves

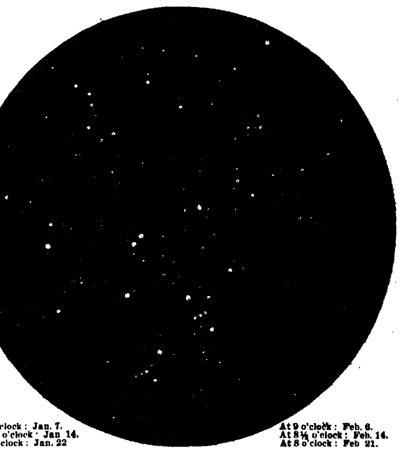
The next nearest satellite to the planet, Rhea, which is a little less than half as far away as Titan, is east of the planet on the evening of the 1st, and at intervals of 4½ days thereafter; but to see it requires a somewhat larger telescope.

A recent bulletin from the Harvard Observatory reports that Prof. Wendell's photometer measurements show that Titan varies in brightness, being 20 per cent fainter when on the farther side of the planet than when on the nearer side. This shows that the satellite always keeps the same side toward the planet, and that this side is darker in color than the other

The remotest satellite, Iapetus, has long been known to vary in a similar manner, but its range is much greater. It is four times as bright when west of the planet than when east of it.

Mars also has satellites—a pair of tiny attendants, very near him—but these are too faint to be seen with any but very large telescopes. The amateur observer must content himself with the study of the more conspicuous markings of the planet's surface, the dark areas, formerly called seas, and the white polar caps. The fact that the dark regions never reflect to us the brilliant patch of sunlight which they would certainly do if they were covered with standing water is a sufficient proof that (at least in the equatorial regions of the planet) they are not really seas.

Prof Barnard, observing with the 60-inch telescope at Mount Wilson during the last opposition, describes their appearance under favorable conditions by saying that the planet "gave one the impression of a globe whose entire surface had been tinted a slight pink color, on which the dark details had been painted with a grayish colored paint, supplied with a very poor brush, producing a shredded or streaky and wispy effect in the darker regions" With a small telescope one can only hope to see the larger outlines of these dark regions, but it is interesting to follow their motion from east to west across the disk as the planet rotates, the change being conspicuous in a couple of hours.



At 11 o'clock: Jan. 7.
At 10½ o'clock: Jan 14.
At 10 o'clock: Jan. 22

At 9 o'clock: Feb. 6.
At 8½ o'clock: Feb. 14.
At 8 o'clock: Feb 21.

At 9½ o'clock: January 29.

NIGHT SKY: JANUARY AND FEBRUARY

As the period of rotation is 24 hours 37 minutes 23 seconds, we see almost the same side of the planet on one night as we did at the same hour on the night before, but not exactly, the difference in the Martian longitude of the central meridian being 9 degrees. The visible region therefore works slowly backward around the disk, taking forty days to return to its original position.

The conspicuous polar caps, which disappear during the Martian summer, and form again during the winter night, are pretty certainly deposits of snow or hoar-frost. The only other substance of which it is at all reasonable to suppose that they may be composed is carbon dioxide, which solidifies at a temperature of about 80 degrees below zero (Cent.). The temperature of the polar regions of Mars during their long day, though probably a good deal lower than that of the Earth's surface, can hardly be as low as this, and it is therefore probable that the polar caps consist of frozen water in some form. It is, however, not certain whether with the amount of heat which Mars receives from the Sun, its polar regions can ever get quite warm enough to melt snow. But Prof. Newcomb cleared up this difficulty some years ago by recalling the fact that snow, like camphor or other volatile solids, may slowly evaporate into dry air at temperatures considerably below the freezing point. This removes the last objection to the theory that the polar caps of Mars are actually layers of snow. They must be very thin to melt off entirely, or evaporate off, under the feeble rays of a Martian summer, and this accords with the fact that Campbell's observations show the quantity of water vapor in the Martian atmosphere to be very small.

At the present opposition, both the Earth and Sun are near the plane of Mars' equator. We see both the northern and southern polar regions of the planet, very much foreshortened, at opposite sides of the disk. The Martian season corresponds to the beginning of April on our planet. The northern pole is just beginning to catch the sunlight, while the southern one is entering upon its long night. The northern polar cap will, therefore, be of considerable size, while the southern regions will be clear of snow.

The Heavens.

In the latter part of the evening, as our map shows, Saturn will be a little west of the meridian, and Mars a little to the east of it, both being very high in the sky. Orion and Canis Major are below them, due south, and shining brilliantly. Far below them is Argo, whose brightest star, Canopus, second only to Sirius in brilliancy, can be seen on the southern horizon from points south of Virginia. Canis Minor, Leo, and Hydra are the most conspicuous constellations in the east, Ursa Major in the northeast, Draco and Ursa Minor in the north, Cassiopeia in the northwest, and Andromeda and Aries in the west, while Perseus and Auriga are almost overhead.

The Planets.

Mercury is morning star at the beginning of the month, rising rather less than an hour before the Sun. Soon afterward, he disappears from the morning sky, and passes through superior conjunction, behind the Sun, on the 28th, to appear as an evening star next month. Venus, too, is a morning star, but is approaching conjunction, and too near the Sun to be easily seen. On the 18th she is in conjunction with Mercury, and the two planets, which are moving in the same direction in the heavens, are within 2 degrees of one another for several days; but both are too near the Sun to be easily seen.

Mars, as we have already mentioned, is in opposition on the 5th. Though very far north, and thus well placed for observation, he is much farther from us than he was at the oppositions of 1907 and 1909—for then he was in the part of his orbit nearest the Sun when the Earth overtook him, and now he is not far from the remotest part. Jupiter is in conjunction with the Sun on the 20th, and is invisible this month. Saturn is in Taurus, visible until shortly before sunrise, as already described.

Uranus is in conjunction with the Sun on the 28th, and cannot be seen. Neptune is in opposition on the 17th, and is well observable with a telescope. His position in the heavens is as follows:

	R. A.	Dec.
January 1	$7^h\ 57^m\ 4.2^s$	$+20°\ 16'\ 24''$
January 17	$7^h\ 55^m\ 12.9^s$	$+20°\ 21'\ 41''$
February 2	$7^h\ 53^m\ 21.1^s$	$+20°\ 26'\ 59''$

The Moon.

The Moon is in her first quarter at 8 A. M. on the 4th, full at midnight on the 11th, in her last quarter at 7 P. M. on the 18th, and new at 2 A. M. on the 26th. She is nearest us on the 15th, and farthest away on the 3rd and the 31st. In her circuit of the sky she passes near Saturn on the 8th, Mars on the 10th, Neptune on the 11th, and Jupiter, Venus, Mercury and Uranus on the afternoon of the 25th and morning of the 26th, within a few hours of each other. At this time all four planets, the Moon and the Sun, all lie within a circle 7 degrees in diameter.

Almost as this article is sent to press, comes a telegram announcing the discovery of another comet by Delavan at La Plata, who was the first to detect Westphal's comet on its return. On December 17th the new comet was in 3 hours 2 minutes right ascension and 7 degrees 25 minutes south declination and was described as "visible in a large telescope," so that it must be faint.

Princeton University Observatory.

The Wright Automatic Stabilizer for Aeroplanes

Merits and Faults of the Patented Device; How the Actual Stabilizer Differs From That of the Patent

By Carl Dienstbach

THERE are two problems still awaiting a really satisfactory solution, for they block the way to a commercial utilization of all the wonderful achievements in aerial navigation. One of these problems involves the invention of the safe flying machine; the other, the economical docking of the speedy mammoth dirigible. Making the aeroplane safe is largely a matter of providing an efficient stabilizer. It is not without significance that the tenth anniversary of the first power-flight is marked by the grant of an American patent for an automatic stabilizer, invented by none other than the Wright brothers, to whom we owe the creation of the first man-carrying motor-driven aeroplane.

It is also significant that this is only the second innovation in the Wright machine of 1908. It is announced that this apparatus will be soon in practical use.

The first departure from the original Wright type was the adoption of a modified "open work" Blériot tail and rear elevator, and the Farman wheels, rather a poor recompense for the wholesale appropriation by the French of the Wright side control. The Wright stabilizer, described in the patent specification, is very simple. Although the apparatus actually built departs somewhat from the patent, still the principle of the invention as revealed in the patent is retained. One is immediately struck with the simplicity of the apparatus—a simplicity which, paradoxically enough, may be the principal obstacle in the attainment of efficiency. If an automatic stabilizer is intended to supply "mechanical brains," it might be expected to show a greater resemblance to a scientific instrument of precision—such as a gyroscopic compass for example.

This stabilizer really embodies two entirely distinct inventions. On the other hand the theoretical conditions of longitudinal stability are absolutely different from those of transverse stability.

The device for obtaining transverse stability mainly embodies the conception of a stabilizing pendulum and its functions. The pendulum *a* is connected with a threeway valve *b*, which by its movement, admits compressed air from an air tank *c* to a servomotor *d*, or allows it to escape from that motor, or locks it in the cylinder and blocks the piston. By means of a connecting rod *e*, working in a slot, and a windlass *j*, the piston pulls on the interconnected cables *g*, which work the warping mechanism and the vertical rudder. The principal novelties are stops *h*, to check the pendulum. They eliminate erratic swinging, but on the other hand restrict this mechanical mind to signifying only "yes" or "no," like a simple Quaker.

There is no grading of effect. The least swing of the pendulum will set the side control going with its maximum energy. A light puff of wind will thus be counteracted with all the force required for the most severe gust. This seems like borrowing trouble. The tremendous action of the side control, having almost nothing to resist it but the considerable inertia of the wide distribution of weight in a transverse direction, which is sufficient to prolong the action of the mechanism considerably, will impart so much momentum to the heavy machine in rocking it around a longitudinal axis, that in spite of instant reversal of the pendulum control, after the horizontal position has been again attained and passed, it must inevitably overshoot the mark, and come to rest only with its side balance worse disturbed in the opposite direction.

It seems for this reason that the machine's return swing under the reversed action of the pendulum should be more violent than the first, because the second action of the pendulum must last longer than the first. And so on should the rocking of the machine become increasingly worse, just as in a very high flower vase with a small base, if it once begins to rock, will increase the amplitude of the swings until they move the center of gravity beyond the support, and the vessel topples over. But there is one compensating action in this process. If an aeroplane is thrown out of side balance by an unwarranted action of the control, it will begin to slide down sideways, just as surely as when the loss of balance is due to unresisted wind force. This sliding in turn will reverse the pendulum's action even before it has brought the machine back to (and fatally beyond) a horizontal position. This seems to explain why a newspaper report has it that "in practice the device was promising but required more experimenting." Certainly its action is not so simple in theory as stated in the patent specification. It could easily be made to work more elastically if a spring were added to restrain the all too ready pendulum.

In real gusts or in turning the side slip becomes detrimental instead of beneficial, causing the mechanism to share the inherent fault of all pendulum devices which was pointed out so clearly by Prof. Prandtl. Probably this device may be developed to supplant the pilot only in calm air, and as it moves the control only by friction it can be overruled in gusts by the ordinary hand lever *i*. It will then resemble Moreau's "aerostable," which also depends on pendulum action in calm air but which is controlled by hand in gusts, the automatic action, however, being graded in exact proportion to the disturbance to be resisted.

The invention may then become only a labor saving device for the pilot—as much of a convenience, as though in a teaching machine with double controls, of which one set can be mechanically overruled by the other, a master pilot had his passenger do the ordinary stabilising and saved his own energy for emergencies.

As the horizontal rudder for maintaining the longitudinal stability is worked by an identical servomotor 1, with connecting rod 2 and windlass 3, which is likewise controlled by a threeway valve 4, defects similar to those of the automatic side control might be expected, although the inventors themselves considered a pendulum, which is affected by any change of speed just as much as by changes of inclination, unsuited for controlling longitudinal stability, and substituted for it what the French would call an "*empennage déplacée.*"

A small plane 5, is mounted at a different angle from the main aeroplanes. Like a non-lifting tail it will receive air pressure from above or below whenever the main planes change their angle of attack, and, as it is allowed to yield by the parallel motion frame 6, which is connected with the threeway valve 4 by a rod and lever 7, it will resist any such change in the angle of attack, not like a tail, by its own surface and leverage, but by the machinery it controls, which machinery promptly sets in motion the horizontal rudder. Apart from such faults as easily ensue from inadequate action of the machinery, such a stabilizing plane is naturally subject to all inherent defects of a stabilizing tail, with one praiseworthy exception.

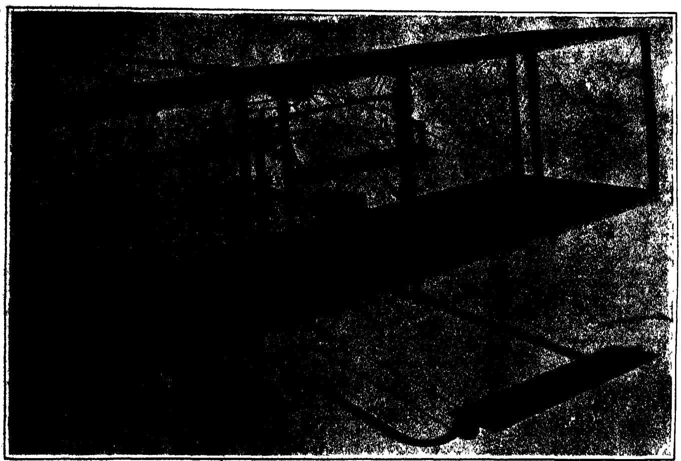
Like the use of a tail it fundamentally presupposes that the stabilizing surface is washed by the same airstream as the main planes. The "internal work of the wind" defeats this theory. But the stabilizing plane here shown has the one great advantage over a tail of being next to the main planes and much more subject to the same up and down trends of the relative wind. Nevertheless, the difference of size remains a stumbling block, just because this plane's mechanical action is so much more violent and sudden than the simple stabilizing effect of a tail.

What we call air pressure on an aeroplane is only an abstract notion because we imagine it as uniform. In reality it is an average of many different and changing impulses on the several units of surface. Consequently, a small plane, even close to a large plane, will not be, as a whole, affected in the same way by the same wind as a large one, as soon as the "internal work of the wind" becomes at all energetic. This is dangerous, if (just as in the case of the pendulum) a slight movement of the plane will set the rudder in full operation. A purely local change of trend in the wind, which does not affect the main planes at all, may thus result in a violent stabilizing action for which there is neither an object nor a resistance. This will start the same increasing oscillations as the pendulum action, softened (in comparison with the lateral stabilizer) by the concentration of weight in a longitudinal direction, but aggravated by the plane, unlike a pendulum, its action not being beneficially reversed by the change of speed resulting from the alternating gliding down and climbing during longitudinal oscillations.

A rather needed remedy would seem to be the addition of a spring restraining the too ready movements of the stabilizing surface and grading its effect. This would represent a very curious analogy to the cushioning of a Pénaud tail, as practised by Chanute-Herring and Langley-Manly for the identical purpose of making a small stabilizing surface less subject to the "internal work of the wind." Manly and Herring have both stated to the writer, each without knowing of the other's experience, that properly adjusting the tension of the spring was the essential thing. A spring would also do away with the need of the counterbalancing weight 8, and its harmful inertia and momentum.

The proper refinement of the device would seem to consist in employing not one comparatively large stabil-

(*Concluded on page 36.*)



The letters refer to the mechanical elements of the transverse stabilizer; the numerals to those of the fore and aft stabilizer. The pendulum rod *A* is connected with a threeway valve *B*, which admits compressed air from a tank *C* to a servo motor *D*, or allows the air to escape from that motor, or locks the air in the cylinder to block the piston. By means of a connecting rod *E*, working in a slot, and a windlass *J*, the piston pulls on the cables *G*, which warp the wings and operate the rear rudder simultaneously. Stops *H* limit the swing of the pendulum. The horizontal rudder for maintaining longitudinal stability is worked by a servo motor 1, connecting rod 2, windlass 3, and threeway valve 4. A small plane 5, mounted at a different angle from the main planes is allowed to yield by the parallel motion frame 6, connected with the threeway valve 4 by a rod and lever 7.

The device invented by the Wrights to balance a flying machine automatically.

Modern Electric Engine Starters and Electric Illumination Systems

Their Significance in Modern Motor Car Construction

By Walter Bannard, M.E.

> *When, more than a dozen years ago, a man with the germ of an idea succeeded in attaching a small electric motor to a heavy gas engine in a way that would permit the engine to be started quickly and easily, he sensed the feeling that some day would come to the owners and operators of motor cars; he expressed in a crude way the thought that in some enlightened day, owners of cars would demand that all the labor attendant upon their operation be eliminated; that the engine be made "self starting" in so far as that is possible. It was the beginning of the mechanical engine starter era. Since then, the mammoth automobile industry has swept fairly rapidly through compressed air starters, ignition starters (under which head come the various acetylene gas and gasoline vapor devices), spring starters and the numerous mechanical contrivances designed to render easier the attainment of the initial explosions by placing at the driver's hand, as he sits in his seat behind the steering wheel, some means whereby he can rotate the crankshaft of his engine. In this article the development of the starter is traced and its importance estimated.*—Editor.

IT was not until two years ago that the engine starting movement gained any real impetus, when practically without exception car manufacturers took to the acetylene starter about as quickly and easily as a duck takes to water; they literally stampeded for it, and for a time all other types of starters dropped almost completely out of sight. But the acetylene starter was inadequate for the reason that it was not 100 per cent efficient. Few car owners were willing to accept its approximate 98 per cent of efficiency as representing a true solution of the engine starting problem. Hence, manufacturers cast about for something else.

The insistent public demand, stimulated by the promise of the acetylene starter, practically forced action which might have been delayed for a considerable period. The compressed air type of starter offered possibilities and a number of manufacturers proceeded to substitute it for the acetylene starter, and, but for the budding of another popular clamor, which once more turned the tide of inventors' efforts, pneumatic devices might now have been in the majority.

But on the head of the demand for starters there came an equally insistent demand for electric lights as representing still another step toward the elimination of the operator's labor, and a palpable improvement over the old style oil lamps. The necessity for providing a dynamo with which to charge the accumulator necessary for electric illumination immediately suggested, or rather reopened the dormant suggestion of a dozen years back, of providing for electrically starting the gasoline engine.

With both dynamo and storage battery in the equipment of the car, it was but a short step to add a tiny electric motor for starting. Hence, passing over the trials and tribulations of those who sought to perfect the application, and succeeded in doing so, the electric engine starter, after scarcely more than two years development, now is supreme. There is scarcely a car manufactured—large or small—that is not fitted with an electric engine starter, and if proof is needed that it has ousted all other types, it need only be added that three very prominent makers of comparatively high-priced cars who always have pinned their faith to the pneumatic starter, have for the first time this year cast it out in favor of electric systems.

Advantages of the Automatic Starter.

It is scarcely necessary to enlarge upon the advantages of the engine starter, quite regardless of its kind: The elimination of manual labor and the attendant risk of injury to the operator; the ability to start the power plant from the driver's seat with all the controls within reach of the man in control; the wiping out of the hazard of motors that stall in front of fast-moving railroad trains or other vehicles; in short, the *safety* of the device. All this is fairly well known.

Nor need any one of average intelligence look at the modern electric system askance as being, perhaps, beyond the ken of the man in the street. Thanks to the efforts of designers, it is, in truth, beautifully simple. It seldom, if ever, requires attention. Therein lies its value. The electric lighting and engine starting system in the abstract includes a storage battery of three, six or nine cells—seldom more—a self-regulation charging generator, which is quite automatic in action, and the starting motor.

The battery, as a rule, is carried in a special frame beneath the body of the car (Fig. 2), though it may be carried on a running board, under a seat or in any other convenient place. In determining its capacity, it is a general practice to consider the necessity for carrying the full lamp load with the engine idle for a given length of time. It must be capable of delivering a heavy current for short periods, as when starting the engine. One well known engine starter of the six-volt type, for example, draws 100 amperes when rotating at 200 revolutions a minute the crankshaft of a four-cylinder engine whose cylinders measure 3¾ by 4½ inches; the gear ratio is seven turns of the starter to one of the engine crankshaft.

The generator must be self regulating and there are several ways in which this may be accomplished. One method that is followed by several well-known makers is to govern the speed of the armature, using a centrifugal device operating a friction clutch; this has been found to work well. Other methods consist of varying the resistance of the field, to govern output, either in the method of winding the machine, or electro-mechanically by means of solenoids, centrifugal devices (Fig. 1) or magnets, a common way being to rely upon the resistance of a pile of carbon disks which are held tightly together under the action of a spring and drawn slightly apart by a magnet inserted in the field circuit (Fig. 8). In one machine, the increasing resistance of iron wire under heat is relied upon to shunt part of the current through what is styled a "bucking coil" when the speed of the armature increases beyond a predetermined limit. To prevent the battery discharging itself through the generator when the engine is stopped, the electro-mechanical cut-out (Fig. 8) is most in use, though some makers use centrifugal devices; the latter are uncommon, however.

Owing to the inherent characteristics of the series wound electric motor, it is peculiarly suited to starter work, and this type is used exclusively. Its most prominent feature and the one that is most valuable is that the torque increases with the load up to a certain limit. Obviously the motor must be wound to stand heavy overloads and must have quick acceleration. Withal it must be as light as possible and occupy the minimum space.

Broadly, electric lighting and engine starting systems can be divided into three general classes, as follows: (1) One unit in which the generator and starting motor are combined in a single machine (Fig. 4); (2) two units in which generator and motor are separately mounted (Fig. 5); (3) single unit, flywheel type, in which motor and generator are combined and the whole mounted with, or in place of, the engine flywheel (Figs. 3, 6 and 9).

Each type has its advantages. Thus, for instance, the two-unit type provides for nearly equal weight distribution of the elements and eliminates the possibility of the derangement of one disrupting the service of the other, though it makes necessary separate mounting and driving. The single unit type centralizes equipment, simplifies mounting and driving, but is open to the objection that both lighting and starting functions may be deranged through failure of either. The flywheel type does away with the necessity for gearing, but must be built into place at the factory of the car maker.

In two-unit outfits there are several ways in which the dynamo can be driven, the preferred method being through the valve gearing either by separate shaft and direct connection (Figs. 10, 11 and 12) or from the camshaft by "silent" chain. The characteristics of the machine largely determine the method, some machines requiring to be driven at comparatively high speed and some at crankshaft speed. Alternative methods are to gear the generator to the propeller shaft by chain or belt, or to drive it from the crankshaft by either chain or belt (Fig. 10). Obviously, where the generator and the starting motor are combined a drive more positive than that afforded by a belt must be provided.

The mounting and driving of the separate starting motor presents other difficulties, for it is plain that there must be some means of disconnecting it *after* it has performed its function. One of the simplest methods is to connect it to the engine through the intermediary of gearing cut in the periphery of the flywheel (Figs. 5 and 14). This method entails the necessity for a sliding pinion on the armature shaft and a means for engaging and disengaging it. Generally, the starting switch and the gear shifting mechanism are interconnected and a supplementary contact provided in the switch to rotate the armature shaft at low speed, first, to facilitate the engagement of the gears. Full depression of the starting lever engages the gears and throws the full current of the battery through the motor. When the engine starts, release of the lever disengages the gears, or else they are automatically "kicked" out of engagement when the peripheral speed of the flywheel exceeds the speed of the driving on the armature shaft.

In one starting motor (Fig. 5) the armature is movable longitudinally and the armature pinion is engaged with the flywheel gear through the solenoid action of the field on the armature when the current is thrown on; a spring disengages the gears. These methods apply, of course, only where the starting motor and generator are separate units.

Other methods include direct connection by shaft through the timing gear train with the interposition of an over-running clutch which lets go when the speed of the driven shaft exceeds that of the driving shaft; or a chain running over a sprocket on the crankshaft or on the propeller or clutch shafts (Fig. 4) may take the place of the shaft drive to the front gear train, the over-running clutch remaining as a matter of course. Latterly, some attempt has been made to incorporate the combined starting motor and generator in the transmission gearset, the connection being through integral, inclosed gearing. This method places the electric unit in a rather awkward position in so far as accessibility is concerned, and has not been largely adopted as yet.

Where the motor and the generator form a single unit positive connection is essential. In this case, the unit is a motor when current is passed through it from the battery, but immediately the gasoline engine takes up its own cycle of operations and drives the motor, it automatically becomes a generator and charges the battery. Generally, an automatic cut-off (Fig. 8) to disconnect the battery from the generator when the engine is stopped is provided, though in one system none is provided. With this latter machine it is impossible for the gasoline engine to be stalled, for instantly the output of the generator drops below that of the battery—as when the engine stops—the generator becomes a motor and drives the gasoline engine. The connection between the electrical unit and the battery is manually made and broken.

In conclusion, the electric engine starter undoubtedly is with us to stay. It has been perfected and refined and its operation rendered so automatic that not even a superficial knowledge of matters electrical is required properly to care for it. Just what the future will bring forth, no man can say. At present, manufacturers are bending their energies to increase efficiency by lightening apparatus, and in the not far distant future it is likely that we shall see all classes of cars electrically lighted and started, from the heaviest to the very lightest—not even excepting the so-called "cyclecar."

The Current Supplement

IN this week's issue of our Supplement Prof. Bateson discusses the subject of heredity with special reference to physical and mental taints.—Charles F. Fraasa, Jr., gives instructions for the construction of a fifty watt transformer.—Prof. Harker writes on the origin of solar electricity.—Dr. J. R. Williams gives us a study of the use of ice and other means of preserving food in the house.—Prof. H. L. Jameson writes on "Biological Science and the Pearling Industry."—The Hardening and Tempering of Steel is the subject of an illustrated article.—Alexander Gracie in his recent James Forrest lecture has brought forward many interesting data on present and past conditions and cost of ocean transport. The salient points of this lecture are summarised for our readers.

Capt. Amundsen, during his recent visit to Copenhagen, announced that he would sail from San Francisco on his north polar journey next June. His vessel, the "Fram," carries a crew of fourteen men, besides the leader and the scientific staff. Provisions for seven years will be taken, though Amundsen hopes to complete his undertaking in four. It is hoped to enter the ice drift in September. The equipment will include two aeroplanes, which Amundsen has bought in the United States. One of the staff recently took a course in aeronautics in France, and Amundsen will himself take a course before starting north. The Norwegian government has contributed 170,000 kroner ($45,560) toward the expedition.

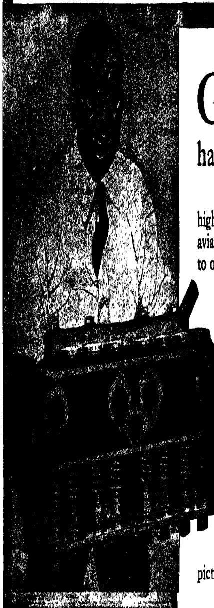
FIG. 1.—*Generator Regulating Method.* A centrifugal device draws an arm over a series of contacts inserting resistance in the field as the speed of the armature is increased, thus maintaining the output practically constant. FIG. 2.—*Storage Battery Mounted Under Floor Boards.* FIG. 3.—*Flywheel Type Motor-generator in Place.* In this type of combined electric lighting and engine starting system the combined motor and generator takes the place of the usual engine flywheel. FIG. 4.—*Bottom View of Chassis Showing Installation of Starting Motor.* The motor is mounted adjacent to the transmission gearset and starts the engine through gears mounted on the clutch shaft. FIG. 5.—*A Typical Modern Electric Lighting and Starting Installation.* Right and left sides of motor showing generator mounting and drive through chain to the camshaft. The armature of the starting motor slides longitudinally, like the core of a solenoid, and engages its pinion with the flywheel gearing; a spring returns the armature to its normal position. FIG. 6.—*Armature of a Flywheel Motor Generator.* FIG. 7.—*Two-unit Lighting and Starting System Complete.* The generator is driven from the timing gear train and the starting motor is geared to the flywheel of the engine. FIG. 8.—*Combined Regulator and Cut-out.* A magnet, in series with the field windings, tends to separate the carbon disks, normally held together by a spring, as the output of the generator increases, thus increasing the resistance of the pile and lowering the output of the generator. The cut-out is an electro-magnetic device to disconnect battery and generator when the engine is stopped. FIG. 9.—*Flywheel Type Motor-generator Disassembled.* Reading from left to right the parts are as follows: Aluminium case with field coils; armature with commutator; brush carrier and brushes; aluminum dust ring. FIG. 10.—*Generator Driven by Chain from the Engine Crank Shaft.* FIG. 11.—*Installation of Generator Driven from Timing Gear Train.* FIG. 12.—*Generator Direct Connected to Timing Gears.* FIG. 13.—*Controller for Both Lighting and Starting Circuits.* FIG. 14.—*Mounting of Combined Lighting and Starting Unit.* As a generator the unit is driven through the pump shaft from the timing gear train; but as a motor, the unit drives the gasoline engine through the intermediary of gearing on the periphery of the flywheel. The operations are automatic.

NEW ELECTRIC STARTERS AND IGNITION DEVICES

"A Mechanical Masterpiece" says Glenn Curtiss



GLENN CURTISS, perhaps the greatest light-engine expert in the world, has just bought a Jeffery Six.

Mr. Curtiss knows what has been accomplished by the use of high-speed light motors. Some of his own greater achievements in aviation have taken place in Europe. He has had ample opportunity to observe the progress made there in light-weight motor construction.

He has seen this idea replace all others in European automobile engine development.

So when Mr. Curtiss buys a Jeffery—the first American car to recognize and adopt the light, high-speed monobloc motor—it is the endorsement of an expert. "The Jeffery," Mr. Curtiss says, "incorporates the latest European practice throughout."

He was one of the first to make inquiry about this remarkable car when the announcement was made. Then he took a demonstration and immediately sent the Thomas B. Jeffery Company a telegram. The text of this telegram is quoted complete on the opposite page under Mr. Curtiss' picture. His Jeffery Six was delivered to him on November 29, 1913.

The light, economical motor used on European cars has proved its correctness in millions of miles of continental running. The heavy motors of some American makers have demonstrated beyond doubt through their costly maintenance expense, their unfitness for cars of moderate price. But these manufacturers cling to the use of the heavy type of motor.

They continue to use it because until now the American motor car buyer has not realized that motor power was not dependent upon motor bulk; and because their plants are equipped to build this type of motor.

We cheerfully acknowledge the supremacy of the light European motor—and we hasten to adopt that which means better service and greater satisfaction to the owners of Jeffery cars.

We are in business to produce the automobile that you want—and we have accomplished that in the Jeffery Four at $1550.

You demanded economy, speed, stamina, lightness and comfort. We built the Jeffery Four to that order.

And believing in that business law which rewards the fit against the unfit, we feel sure that the Jeffery Four will in a very short time supplant a great many of the heavy American models.

Already we have sold hundreds of cars to men who could pay more, but who found they could not buy better.

They had declared themselves for flexibility. Jeffery gave them a car that would make 40 miles an hour within 20 seconds, from a standing start.

They had declared themselves for lightness. Jeffery produced a car that weighs but 2870 pounds.

They had declared themselves for power. Jeffery offered a light, fast motor that develops 42 horsepower.

They asked economy. Jeffery motors are high efficiency motors; burning little gas; burning it completely, quickly and economically.

Jeffery lightness (2870) means a long life to tires; often six or eight thousand miles per set.

A Jeffery horsepower has to pull but 60 pounds of car—other motors have to pull from 80 to 100.

And above all, the discriminating buyer who has owned other cars, and had discovered the sacrifices necessary to low price, demanded comfort.

"It can't be done," said Jeffery dealers—

"It is impossible," said the owners whose specifications we set out to incorporate.

Jeffery did it.

And because he proved that we had met every demand for lightness, speed, power, economy and comfort, the result is mighty gratifying to us.

The best dealers everywhere in the country are organizing new companies and dropping other lines to sell this car, and the motor car buying public who have been paying much more for big, heavy, uneconomical cars, and much less for cheap, uncomfortable cars, are driving Jeffery cars this season.

The Jeffery Six is a duplicate of the wonderful Jeffery Four, except for size. The cylinders are cast in pairs. This car, which sells at $2,250, is in a great many ways as remarkable among Sixes as its smaller brother is among the Fours. We built it for those who will drive nothing but a Jeffrey car, but who prefer a Six. It is light—actual scale weight, 3,570 pounds, with full equipment. We made it luxurious and beautiful without making it extravagant. We know that a better Six cannot be built.

The motor—3¾ x 5¼—develops 48 horsepower. The bearings are imported annular ball throughout. The ignition is Bosch Duplex and the starting and lighting system is the U-S-L of course. Wheel base, 128 inches, and wheels 36x4½—on enclosed cars 37x5—full floating rear axle. Rayfield carburetor, Warner autometer, ammeter, engine driven power tire pump, Rothschild body with extra wide doors and low, deep seats. This car is made with five-passenger touring or two-passenger roadster body at $2250; six-passenger at $2300; Sedan, five-passenger, $3250, and Limousine, at $3700.

The Thomas B. Jeffery Company
Main Office and Works, Kenosha, Wisconsin

Specifications of Jeffery Four $1550

U-S-L starting and lighting, without chains, gears, bearings or belts. Left hand drive and center control.

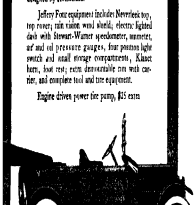
Imported annular ball bearings throughout; Spicer universal joints; combination force feed and splash oiling system. (Speed up to forty miles an hour, shut off your engine and coast half a mile.) Leather ring universal between clutch and transmission; four forward speed transmission—the lightest and easiest to operate

High grade, full floating type rear axle, on imported annular ball bearings—a delight to the motor wise. Vanadium steel rear axle drive shafts, front axles, springs and steering knuckles.

Bosch duplex ignition; Rayfield carburetor; pressure feed gasoline tank with gauges on tank and dash; demountable rim; advanced type of body designed by Rothschild.

Jeffery Four equipment includes Neverleek top, top cover; rain vision wind shield; electric lighted dash with Stewart-Warner speedometer, ammeter, air and oil pressure gauges, four position light switch and small storage compartments, Klaxet horn, foot rest; extra demountable rim with carrier, and complete tool and tire equipment.

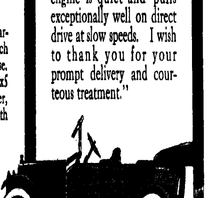
Engine driven power tire pump, $25 extra



Jeffery Four $1550

Glenn Curtiss Says:

"I have been running the new Jeffery Six, and I am glad to report to you that the car is as good as it looks and a mechanical masterpiece. The machine is up-to-date in every respect and incorporates the latest European practice throughout. It has plenty of power and speed and is easy riding and very easy to handle. The engine is quiet and pulls exceptionally well on direct drive at slow speeds. I wish to thank you for your prompt delivery and courteous treatment."



Jeffery Six $2250

Making the Automobile Comfortable in Winter

By George Petman

IN at least one respect the motor world of to-day is vastly different from the motor world of yesterday. Whereas not more than a year or so ago the motorist who braved every summer storm, packed his car away —almost literally in moth balls—during the winter months when Jack Frost held sway, now drives the year around. It is a tendency that is becoming more and more marked each year. In a great many cases those who purchase cars when the new models come through in the fall or in the late summer, purchase two bodies to fit the one chassis—an open touring body for use during the remainder of the summer and a closed body, or either the limousine or landaulet or coupé type for use in the winter months. But even where two bodies are not purchased the all-year motorist is becoming ever more prominent, and there are abundant reasons why this should be so.

In the first place, the open car of a few years ago was an open one in very truth—it afforded little protection to those who occupied the tonneau seats and even less to the driver and his "left hand man." The day of the partly closed forward compartment had not yet dawned. To tour in winter then meant swathing one's self in layer upon layer of heavy robes until the *tout ensemble* presented more the appearance of a mummy than of anything else. And even when it was possible to prevent chills chasing themselves up and down one's back, real comfort still perched alluringly on the horizon.

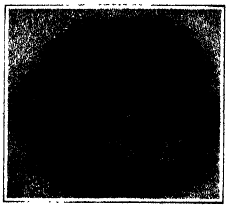
With the advent of the closed front touring body, conditions were very much improved. Chill blasts from the sides were effectually stopped, and at least one layer of robes was rendered unnecessary Later, manufacturers saw light in the deep scuttle dash that so long had been in vogue in England and on the Continent, and it slowly commenced to appear on American cars. Now, there scarcely is a car marketed that has not a scuttle dash, and certainly there are none that are minus front doors

Strangely enough, however, little attention has been paid to the necessity for increasing the comfort of those who ride in the tonneau seats. Although the driver and the person who sits beside him may now ride in comparative comfort when the wintry winds do blow, those who ride in the tonneau still are constrained to disguise themselves with robes and furs. And this is all the more remarkable by reason of the fact that of the two seats, the tonneau seat is by far the colder. No doubt this is due in part to the fact that little or no heat from the engine penetrates to the back of the car. Another factor which undoubtedly contributes to the chill atmosphere that pervades the tonneau of most cars is that the windshield and the scuttle and the lines of the body tend to produce eddy currents which are swept over the front seats and down into the space between the back of the driver's seat and the back of the car.

As far as is known, no manufacturer thus far has made any provision for warming the tonneau of his car during cold weather, though manifestly there is a crying need for some device that will contribute to the comfort of passengers in the rear seats. A simple exhaust gas heater or a radiator receiving its warmth from the water in the engine jackets would serve the purpose excellently, and either method has the advantage that it is neither expensive to install nor to maintain. To warm the driver's compartment is considerably simpler than to warm the tonneau, of course, and this probably accounts for the greater attention that has been paid to the comfort of the driver. The simplest method of providing warmth is to insert a small grating in the floorboard and to provide it with a means whereby the openings can be varied to suit the temperature requirements of the driver. Heat generated by the engine then would be forced through the grating by the draft created by the cooling fan, and as exhaust products cannot escape beneath the engine hood no objection can be found to this method.

Devices of the kind tend to maintain only the lower extremities of the body at their normal temperature, of course, and as it is absolutely essential that the driver's hands be on the steering wheel during the whole of the time the vehicle is in motion, some other means of keeping his hands warm must be adopted. For this purpose there has been placed on the market an exhaust gas heated steering wheel, though it has not come into very great use owing to its complication, slight as it is in fact. Much preferred are the electrically heated steering wheels that are available. These devices operate on exactly the same principle as the ordinary electric heater except that being considerably smaller, they consume very much less current. In one type, the wheel complete is supplied by the maker and may be placed at the top of the steering post instead of the regular wheel. In another type, two grips containing the heating units lace to the existing wheel and therefore can be removed when not needed. Another device that only recently has come into fairly general use—as a matter of fact, all these devices are new—is the electrically heated glove a picture of which is reproduced herewith. The gloves contain the heating units coiled around inside the fingers and terminating in contacts so arranged that a natural grip on the steering wheel brings them against other contacts (on the wheel) connected with the source of energy which usually is the lighting storage battery. Thus, shifting the hands slightly disturbs the connection and permits the gloves to cool slightly in case their temperature becomes too high for comfort.

An electrically heated glove and heating units laced to wheel.



Electrically heated steering wheel wound with heating coils.

Electrically heated shoes—or overshoes—have yet to put in an appearance, though the necessity is not as great for the reason, already made plain, that sufficient heat to keep the driver's feet warm can be obtained from the engine. But to those who ride in the tonneau they would prove a boon indeed.

Lessening the Fuel Cost of Motors

By the Paris Correspondent of the Scientific American

SHOULD the comparatively valueless naphthalene come into general use for internal combustion motors, it will almost work a revolution in the cost of fuel in this most extensive field, so that the following account of recent tests made with the combustible in France should prove of interest. It is given by M. Ventou-Duclaux, a prominent member of the Automobile Club technical commission, and an authority on all such subjects. The tests were made upon a Renault motor car of the taxi-auto type, the motor having been transformed for the present use, it being a 12 horsepower 2 cylinder, 102 millimeters bore and 120 stroke. The special devices for naphthalene fuel were the result of two years study by Engineer G. Mohr, and they are shown in the illustrations.

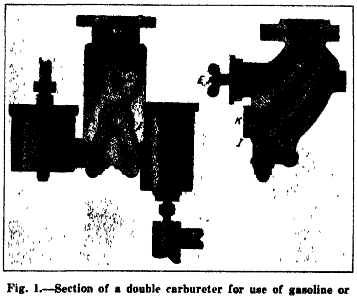


Fig. 1.—Section of a double carbureter for use of gasoline or naphthalene.

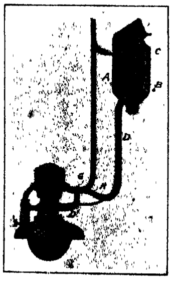

Fig. 2.—Apparatus for liquefying naphthalene.

The naphthalene is melted in a vessel heated by the exhaust gases of the motor (Fig. 2), and to this end the exhaust pipe is made up in a worm tube inside the vessel *A*. Inside is a filter *C* of wire gauze, into which the solid naphthalene is placed, thus retaining solid particles. When melted it runs down by the small tube *B*, which lies close to the hot exhaust pipe *D* so as to allow the naphthalene to reach the carbureter in the melted state. The carbureter is also kept hot by the exhaust gases by way of D^1 and the circulation of hot gases is regulated by the vanes *G* and *H*.

In Fig. 1 is seen the special carbureter, it being made double for the use of gasoline or naphthalene. On the left is the usual float-feed gasoline carbureter. The second one has also a float. The two spray nozzles *I* and I^1 work within a common chamber *K*, this chamber being placed between the jacket *L* having hot gas circulation and a second chamber *S* above, for extra air inlet. The naphthalene spray nozzle is seen at *I*, and air is drawn in for the mixture at *K*. Extra air is admitted in *S* by working the screw *E*.

The combustible used in this case is crude naphthalene whose price in the region of Paris is $1.20 per 100 kilogrammes (220.5 pounds). The following tests with the automobile were made under the direction of the Arts and Crafts Institution of Paris (Conservatoire des Arts et Metiers) and took place on the road between St. Germain and Vernon, on a distance of 52.7 kilometers (32.74 miles) each way, or a total of 105.4 kilometers (65.5 miles). The motor had been started up by gasoline a few minutes beforehand, so that the run could be made on the other fuel alone. The following results were obtained: Duration of test, 3 hours 19 minutes 30 seconds; stops (motor stopped), 15 minutes 30 seconds; net time of test, 3 hours 4 minutes; distance covered, 65.5 miles; state of road, good macadam route with average grades. Mean speed, 34.4 kilometers per hour (21.4 miles); highest speed taken (upon 1 kilometer: 0.62 mile), 42.3 kilometers per hour (26.3 miles); consumption of naphthalene, 14.906 kilogrammes (32.95 pounds).

From the above figures, the consumption of fuel is 14.228 kilogrammes (31.30 pounds) for 100 kilometers (62 1 miles). As regards working of the motor, the following favorable observations were made. At the beginning of the test the motor was started up without difficulty with naphthalene as fuel, after the use of gasoline in the cylinders. During the trial the motor ran regularly as usual and no failures or shocks were noted. After each stop, the motor could be started up easily without using gasoline. At the exhaust there is little or no smoke, except in the up-grades. On the next day it was found that the motor was clean inside and in good working shape, without deposits. It is specially noticed that there were no deposits of naphthalene in the crank-box. A second test was made to show the time needed to start up the motor. With the motor cold, it was started on gasoline, and after 13 minutes 37 seconds it could be run on the other fuel. At this time it was seen that the solid material in the chamber was not all melted. The motor was stopped during ten minutes and was then able to start upon naphthalene without difficulty. With a 16-minute stop it was required to use gasoline in order to start again.

The figures given show that the cost of fuel on a basis of 100 kilometers is: 14.228 × 0.06 = 0.85 franc (16.5 cents), or for 100 miles, $0.28. By adding the small amount of gasoline used, this can amount to 1.00 franc, or even less ($0.32 per 100 miles), while the same motor would have consumed 10 liters (2.64 gallons) of gasoline, representing a cost for 100 kilometers of 5 francs (or for 100 miles, $1.60). The difference between these figures will show the great economy realized. It is interesting to note that the *ensemble* of motor, carburetor and heating device does not reach more than 22 pounds per horse-power. The present tests allow of predicting other applications of the new fuel, such as for power wagons especially, and it may prove to be of great use in this field in cases where the power wagon is to transport material having a low value. For use in stationary engines it will also be available, and the cost for power will now be only 0.4 cent per horse-power hour. Fire risk will now be much less, for the gasoline tank is a very small one and besides can be removed when not in use for motor starting.

New Materials for Paper Making

WE are accustomed to regard paper as a thing of very little intrinsic value, and to treat it as one of the negligible details of business. For all that it is one of the most important and necessary articles of modern industry. The report of the Bureau of the Census places it as twenty-first on the list of manufactured products rated according to value. In the year 1909, the value of the paper and paper pulp manufactured in the United States was $267,657,000. This being the year 1913, the value is considerably greater.

Each year finds new uses to which this valuable material may be put, and hence each year the price of paper and of pulp rises. At present the chief source of pulp for the common grades of paper is the wood of certain pine, spruce and fir trees. The supply is limited, and the rate of consumption is increasing so rapidly that the entire supply is threatened with exhaustion in a few decades. Such is the ever-increasing demand for wood pulp that scientific men and inventors have been spurred on to search for substitutes for wood pulp. There can be no doubt that great pecuniary reward will be earned by the man who devises new processes and machinery which will make the paper manufacturer independent of the wood pulp supply.

A material suitable for the paper manufacturer's purpose must first of all yield a fiber that will "felt," in other words a fiber that will interlock and cohere in a homogeneous sheet. Many vegetable substances will meet this requirement, but a second and more practical consideration enters which is not so easily met. The substance must be such that the material from which the fiber is to be extracted may be readily broken up, so as to liberate the fibers. Moreover, the material must be available in sufficient quantity to make manufacture commercially successful. Lastly, the resultant product must be so cheap as to compete successfully with the paper made from wood pulp.

Numerous attempts have been made to employ the various vegetable by-products, such as sugar cane stalks, sugar beet pulp, etc. Until these products can be made into paper at a price of less than 3 cents a pound, there is no immediate hope of commercial success.

Before wood pulp was introduced about forty years ago, straw was largely used to furnish the fiber. But as it was possible to manufacture wood pulp paper at considerably less cost, this source of material was largely abandoned. However, it is quite possible that as soon as the price of wood pulp becomes so great as to make the manufacture of straw pulp profitable, the industry will be revived.

Prof. Reinke of Brunswick, Germany, has recently patented a process for obtaining cellulose from the refuse of tanning factories, especially pea and bean straw, and the straw and trimmings of asparagus. The trimmings, which constitute about 30 per cent of the weight of asparagus as it comes to the factory, decay very rapidly and have hitherto been used almost solely as a fertilizer, although they have been dried and employed as packing material to a small extent. A sort of wrapping paper made from them as an experiment, proved to be unsalable. Flavoring extracts are made from these trimmings, but Prof. Reinke's experiments have proved that the refuse of this industry can also be converted into cellulose. Still larger quantities of cellulose can be produced by heating asparagus straw or after-growth with sulphurous acid or soda lye in autoclaves, under four to six atmospheres pressure for from one hour to three hours. The cellulose is obtained in fiber of various lengths, and can be converted by grinding, washing, treating with permanganate, sulphurous acid, and the like, into material suitable for the production of paper, felt and other cellulose products.

A lucrative cellulose industry might be established by co-operation between growers and canners of asparagus. According to Prof. Reinke the factory trimmings yield 1.8 per cent of cellulose, amounting to about 15 pounds of cellulose per acre, while the asparagus straw (vines) yields 9 per cent, or about 174 pounds of cellulose per acre.

The production of cellulose from pea and bean straw is of great economic importance, because these materials have hitherto been almost worthless. Pea straw is used in small quantities as fodder, but it is usually plowed under. Bean straw is burned, and the ash has little value as fertilizer. Prof. Reinke has obtained cellulose of good quality by macerating both of these materials with lye under pressure. The process is similar to that employed from asparagus, but the product is superior both in quality and in quantity and is suitable for the manufacture of nitro-cellulose, viscose, etc., as well as for paper making. Pea straw yields 24 per cent, bean straw 33 per cent of cellulose, but this difference is more than compensated by the difference in the crop of straw per acre, so that one acre of peas yields 127 pounds, and an acre of beans 116 pounds of cellulose.

It has been proposed to use various weeds, grasses, cornstalks, sugar cane stalks, and many other vegetable matters, to furnish fiber. But in comparison with pulp wood, these materials are still commercially negligible. About forty-five to fifty per cent of the material of the wood can be made into a fiber paper. Ordinary straw yields about forty-five per cent, while cornstalks, grasses, etc., do not generally yield more than 25 per cent.

A recent report by Dr. Frederick Finch Strong on the manufacture of paper from a species of marsh grass, gives promise of a material that may become of commercial importance as the price of paper and wood pulp increases. The source of the fiber is a kind of marsh grass known as "big saw grass." This grows in immense quantities in the everglades of Florida. The largest patch extends over an area of about six hundred square miles. The stalks grow about four feet high, and the blades or leaves grow about an inch wide and up to about six feet in length. The leaf has a very sharp saw edge that cuts the flesh like a razor. It is possible to harvest two or three crops of this grass each year, and it would be very easy to obtain enough of the material to make commercial working successful. The method of preparing this grass for pulping differs from that used in making wood or straw pulp The material is taken *green* and instead of being chemically digested, or ground, it is run through a mechanical digester that strips off the green outer covering and exposes the fibers. Soda or sulphite solution will not attack the green fleshy cover, but as soon as it is removed, the fiber bundles readily disintegrate into fibers under the action of a weak caustic solution and low pressure steam. The fiber that results can be made into a great variety of good papers.

At the February meeting of the London Society of Arts, Beadle and Stevens described Routledge's experiments in the utilization of bamboo fiber for paper making. Raith demonstrated in 1908 that unbleached bamboo pulp could be produced at a cost of about $30 a ton, one third of which sum is required for chemicals, as bamboo canes need a preliminary cleaning in order to enable the product to be bleached well. Beadle and Stevens also mentioned as exceedingly well adapted to paper making, the fibers of *Hedychium coronarium*, the "sweet snow" or "wreath flower," a plant which grows in India, Central and South America, and West Africa

Another fiber-producing plant is a *Cryptostegia*, which is cultivated in the Bahama Islands and attains a height of 13 feet or more in one year. Excellent paper pulp closely resembling that obtained from rags is yielded by *Ponzolria hypolenca*, a plant which grows in German Southeast Africa, but is not cultivated, although it certainly could be grown with profit.

The success of Reinke's experiments with asparagus, pea and bean straw suggests the advisability of applying the same process to other material which is now of little or no value—for example, the fallen leaves of deciduous trees The chlorophyl, carbohydrates and most of the mineral ingredients of the leaves are drawn back into the trunk before the leaves fall. The fallen leaves contain little else than cellulose, which has only slight value as a fertilizer. The toughness of the fibers is proved by the fact that the skeletons of the leaves do no decay until late in winter.

Recently a scheme was proposed in the handling of sugar cane that would allow of the extraction of the sugar, and the utilization of the fibers of the stalks. It was proposed to shred the cane on the plantations into a kind of coarse silage. This shredded material was then to be dried at the plantations, and shipped to the sugar mills, where the paper mill is also located. Here the sugar is to be extracted, and the stalk's material made into paper. But it is found that by the time the planter buys the coal to dry the cane, and pays the cost of transportation, he has paid out more than the fiber is worth. This process loses sight of the fact that cane stalks are used as fuel in sugar mills, thus saving the cost of any other fuel that would have to be employed in extracting the sugar.

A number of inventors have found ways of using the wood of the southern pine in making paper fibers. The wood of these trees is very resinous, and as a consequence the fibers are very hard to digest by the use of any of the well-known methods. By suitable treatment it is possible to break up this resinous binder, extract the pulp and save the resin. It is claimed by some inventors that the resins alone will pay for the cost of the extraction of the fibers, but for all that it seems that these processes cannot compete with the northern wood pulp processes.

A plant has been established in Louisiana to use sawmill shavings. A heavy wrapping paper is manufactured, and the plant saves the by-product of turpentine and resin.

One inventor, C. L. Weiberg (patent No. 1,025,435) has devised a process for utilizing the fibers from banana stems, tobacco, hemp, okra and seagrass, and several inventors have suggested processes for extracting fibers from peat. But the laws of economics are as inflexible as laws of nature, and until the price of the northern wood pulp rises to a higher figure than at present, these processes must wait for commercial development, serving meanwhile little more than reserve processes.

Wireless Telegraphy in the New York Fire Department

ALMOST simultaneously with the successful application of wireless telegraphy to moving trains for signalling and other purposes of communication, comes the announcement of its use in the fire alarm telegraph bureau of a great city with extensive water front and large shipping interests.

A successful test recently has been made of an installation at Fire Headquarters, New York city, whereby an operator at the central station of the telegraph bureau is able to maintain communication with a fleet of fireboats as they proceed about the waters of the harbor in answering an alarm, or when they are in actual service, as, for example, at a ship on fire at anchor. This new equipment involves a simple installation of wireless apparatus at Fire Headquarters in East Sixty-seventh Street, with an operator always on duty and a similar equipment on the fireboats which, so long as they remain at their station, are in touch with the telegraph bureau by the fire alarm telegraph and by telephone As yet the equipment has been provided only for the large fireboat "James Duane," but it has worked so successfully and proved its utility that it doubtless will be extended to others of the fleet of ten fireboats which the city of New York maintains to protect its shipping and the water front.

The apparatus installed has an effective working range of about 25 miles, and is capable of being tuned to any wave length. Just as soon as the fireboat pulls out into the stream to answer an alarm, the operator on board goes to his instruments and establishes communication with headquarters. The fireboats, on account of their great pumping and hose capacity, respond to a large number of alarms from boxes on, or near the water front, and in so doing make trips of considerable length Many of these alarms are inconsequential, or even false, and the first land engine company to arrive often deals with the fire satisfactorily. As soon as the fire is put out, or the false alarm investigated, the officer in charge telegraphs the fact to fire headquarters and this may be within a very few minutes of sending the original alarm. With the new system, if there is no need for the services of a fireboat, the wireless operator at the central telegraph station transmits an order to the boat on its way and it returns to its station, thus obviating the useless journey with the consumption of coal, which is no small item, and also what is more important, the leaving of territory unprotected. This is indeed serious, as one or more fireboats may proceed a considerable distance in answering an alarm of no importance, while in their absence there may be an outbreak of fire where their services are needed. One or two occasions of this kind have occurred in New York within the last year so that the danger is more real than fancied

At a recent demonstration at which a representative of the SCIENTIFIC AMERICAN was present, an alarm of fire from a box at Ninety-sixth Street and West End Avenue was turned in That being a station at which the fireboat was due, the "James Duane" immediately got under way and proceeded out in the stream and up the Hudson River. Ten minutes later the wireless operator at headquarters, as if it had been a false alarm, sent out a message ordering the captain of the "James Duane" to return to quarters and a confirmation of the receipt of this order was immediately received A few minutes later the commanding officer of the fireboat reported to headquarters over the ordinary telephone that his company had returned and that the messages had been received promptly and correctly.

In addition to the usefulness of wireless on the fireboats already suggested, the possibility of receiving wireless messages from ships at sea at fire headquarters and sending out assistance to vessels approaching the port with fires below their hatches, is also to be considered, as well as the summoning of assistance from ships at anchor where fire breaks out suddenly. As now even cargo steamers are generally provided with wireless equipment, it would be possible to summon assistance within a very few moments after a fire is discovered that the crew cannot cope with. Whether the usefulness of wireless on the fireboats protecting our large harbors may lead to their availability for deep sea service is, of course, problematical, but it will be seen that this new adjunct is not without possibilities in this direction.

Tobacco Growing in England.—The experiment of introducing the cultivation of tobacco in England is being carried out by an organization known as the Tobacco Growers' Society under the supervision of an expert from Rothamsted. The principal plantation is in Hampshire, where a large curing barn has been built. Ireland has now about 150 acres under tobacco, and small experiments of the same sort are under way in Scotland and Wales.

A Quick Reference Table for Commercial Motor Vehicle Buyers

A List of American Motor Trucks and Delivery Wagons Arranged According to Carrying Capacity

Compiled by C. Edward Palmer

A BUSINESS man buys a motor truck which, in his opinion, is best suited to handle his particular class of goods. Hence he is usually concerned more with tonnage than with price. In the commercial vehicle table printed on this page, truck manufacturers are, therefore, listed alphabetically with their products and their products are arranged according to tonnage.

Since the majority of gasoline trucks have four-cylinder motors, it has not been considered necessary to provide a separate column in which the number of cylinders is mentioned. Only the tonnage, horse-power and price are given. The most representative models of each manufacturer are listed and the prices, with very few exceptions, include the chassis only. Bodies in a great variety of forms are furnished by the manufacturers at prices ranging from $100 upward.

The majority of truck manufacturers are willing to sell to small merchants on easy payments and to supervise the installation of motor service.

GASOLINE COMMERCIAL VEHICLES

Name of Vehicle.	Name and Address of Manufacturer.	Tons Capacity, Horse-power and Price.						
		Under 1 ton.	1-1½.	2-2½.	3-3½.	4.	5.	6 and over.
A. & R	Abendroth & Root Manufacturing Co , Newburgh, N. Y.				3, 36, $3,500	4, 36, $3,700	5, 53, $4,350	
Adams	Adams Bros Co , Findlay, O		1, 30, $2,100	2, 30, $2,500				
Admiral	Admiral Motor Car Co., St Louis, Mo		1, 25, $1,475					
A I. C	Ice Manufacturing Co , New York City						5, 29, $3,500	
Alter	Cincinnati Motor Manufacturing Co., Cincinnati, O	½, 33, $1,350						
Armleder	Armleder Co , Cincinnati, O		1, 28, $2,200	2½,34, $2,500				
Atterbury	Atterbury Motor Car Co., Buffalo, N Y.	¾, 25, $1,500	1, 30, $2,000	2, 40, $2,650	3, 50, $3,350		5, 50, $4,250	
Autocar	The Autocar Co., Ardmore, Pa		1½,18, $1,650					
Available	Available Truck Co , Chicago, Ill		1, 28, $1,275					
Avery	Avery Co , Peoria, Ill		1½, 40 (Price	s on applicati	on)			
Barker	C L Barker, Norwalk, Conn		1, 35, $2,000					
Beck	Beck & Son, Cedar Rapids, Ia		1½,40, $1,500		3, 50, $1,800			
Best	Durant-Dort Carriage Co , Flint, Mich	½, 13, $750						
Bessemer	Bessemer Motor Truck Co., Grove City, Pa	¾, 22, $1,250	1½,30, $2,100					
Blair	Blair Manufacturing Co., Newark, O.		1½,35, $2,850	2½,40, $3,250	3½,40, $3,750			
Brockway	Brockway Motor Truck Co., Cortland, N Y	½, 20, $900	1½,30, $1,750					
Brown	Brown Commerical Car Co , Peru, Ind.	¾, 23, $1,650	1, 23, $1,850					
Buick	Buick Motor Co., Flint, Mich	½, 15, $1,000	1, 15, $1,125					
Butler	Huselton Motor Co., Butler, Pa.	¾, 30, $1,650						
Casey	The F A Casey Co., Billerica, Mass.		1, 30, $1,650	2½,40, $2,700		4, 40, $3,500		
Chase	Chase Motor Truck Co., Syracuse, N. Y	½, 34, $855	1, 34, $1,200	2, 40, $2,100				
Coleman	Coleman Motor Truck Co , Ilion, N. Y.		1½,—, $1,950	2, —, $2,400				
Commerce	Commerce Motor Car Co , Detroit, Mich	½, 15, $875						
Continental	Continental Truck Manufacturing Co., Superior, Wis.		1½,35, $1,500					
Corbitt	Corbitt Automobile Co., Henderson, N C		1½,23, $2,000					
Couple-Gear	Couple-Gear Wheel Co., Grand Rapids, Mich				3½,24, $4,250	(4 wheel drive	)5,36, $4,850	(4 wheel drive)
Crow Elk-Hart	Crow Motor Car Co , Elkhart, Ind	½, 33, $950						
Crown	Crown Commercial Car Co., Milwaukee, Wis	¾, 26, $1,350	1, 32, $2,300	2, 35, $2,800	3, 40, $3,300	4, 45, $4,000		6, 50, $4,500
Danielson	Danielson Engine Works, Chicago, Ill		1½,28, $2,000				5, 45, $4,500	
Dart	Dart Manufacturing Co , Waterloo, Ia	½, 20, $715	1, 30, $1,300	2, 40, $1,775				
Dayton	Dayton Automobile Truck Co , Dayton, O.		1, 25, $1,500	2, 30, $2,650	3, 30, $3,400	4, 40, $3,900	5, 40, $4,500	7, 64, $5,900

A Quick Reference Table for Commercial Motor Vehicle Buyers—Concluded

Name of Vehicle.	Name and Address of Manufacturer.	Tons Capacity, Horse-power and Price.						
		Under 1 ton.	1-1½.	2-2½.	3-3½.	4.	5.	6 and over
Trojan	Toledo Carriage Co., Toledo, O.	½, —, $1,500						
Tulsa	Tulsa Automobile Manufacturing Co., Tulsa, Okla.	¾, 42, $1,250						
U. S.	United States Motor Truck Co., Cincinnati, O.			2, 27, $2,800	3, 32, $3,500			
Universal	Universal Motor Truck Co., Detroit, Mich.		1½, 23, $1,950		3, 25, $3,400			
Van Winkle	Van Winkle Motor Truck Co., Atlanta, Ga.		1½, 30, $2,250	2½, 30, $2,800	3½, 45, $3,500			
Veerac	Veerac Motor Co., Anoka, Minn.	¾, 20, $925.						
Velie	Velie Motor Vehicle Co., Moline, Ill.	¾, 32, $1,600		2, 32, $2,850	3, 32, $3,350			
Vulcan	Driggs-Seabury Ord. Corp., Sharon, Pa			2, 26, $2,750	3, 26, $3,250	4, 30, $4,000	5, 30, $4,500	7, 36, $6,000
Wade	Wade Commercial Car Co., Holly, Mich.	2/5, 8, $375.						
Wagenhals	Wagenhals Motor Co., Detroit, Mich.	2/5, 20, $690.						
Ware	Ware Motor Vehicle Co., St. Paul, Minn.			2, 40, $3,000	(4 wheel driv	e)		
Wichita	Wichita Falls Motor Co., Wichita Falls, Texas		1, 30, $1,650	2, 35, $2,100	3½, 50, $3,250			
White	The White Co., Cleveland, O.	¾, 28, $2,100	1½, 28, $3,000		3, 23, $3,700		5, 28, $4,500	
White Star	White Star Motor Co., Brooklyn, N. Y.		1, 30, $2,000	2, 35, $2,750	3, 40, $3,400	4, 45, $3,700	5, 45, $4,200	
Wilcox	H. E. Wilcox Motor Car Co., Minneapolis, Minn.		1, 27	2, 29	3, 29	(Prices on ap	plication)	
Wilt	Wilt Engine and Truck Co., Buffalo, N. Y.	¾, 23, $1,650		2, 32, $3,800				
Willys-Utility	Gramm Motor Truck Co., Lima, O.	¾, 27, $1,250						
Wit-Will	Wit-Will Co., Washington, D. C.		1, 35	2, 42		4, 50	(Prices on ap	plication)

Since the majority of the gasoline commercial vehicles have 4-cylinder motors, this figure has been omitted from the above table. The first figure in each case represents the tons capacity, the second figure the horse-power, and the third the price. Only the most representative models of each manufacturer are listed. The prices for the most part for the chassis only. Bodies are usually made to order.

Electric Commercial Vehicles

As in the Gasoline Commercial Vehicle list, the prices are almost invariably for the chassis only. Bodies are built to order.

Name of Vehicle.	Name and Address of Manufacturer	Tons Capacity, Horse-power and Price						
		Under 1 Ton.	1-1½	2-2½.	3-3½	4	5	6 and over.
Argo	Argo Electric Vehicle Co., Saginaw, Mich	½, $1,000	1, $2,150					
Atlantic	Atlantic Vehicle Co., New York City	½, $1,960	1, $2,200.	2, $2,750.	3½, $3,375.		5, $3,825	
Baker	Baker Motor Vehicle Co., Cleveland, O.	½, $1,900.	1, $2,300.	2, $2,800	3½, $3,500			
Borland	Borland-Grannis Co., Chicago, Ill.	¾, $2,100						
Buffalo	Buffalo Electric Vehicle Co., Buffalo, N. Y.		1, $2,400					
Capitol	Capitol Truck Manufacturing Co., Denver, Colo.	½, $1,800						
Couple Gear	Couple Gear Freight Wheel Co., Grand Rapids, Mich				3, $3,650		5, $4,150 (Front	wheel drive)
Couple Gear	Couple Gear Freight Wheel Co., Grand Rapids, Mich				3½, $4,400		5, $5,000 (Four	wheel drive)
C. T.	Commercial Truck Company of America, Philadelphia, Pa.	½, $1,040	1, $2,345	2, $3,050	3½, $3,880		5, $4,310	
Dayton	Dayton Electric Car Co., Dayton, O	½, $1,400.						
Detroit	Anderson Electric Car Co., Detroit, Mich	½, $2,350	1, $2,800	2, $3,750	3, $5,000		5, $5,500	
Eldridge	Eldridge Manufacturing Co., Boston, Mass			2,	3,		5,	7, 10, *
G. M. C.	General Motors Truck Co., Pontiac, Mich	½, $1,400.	1, $1,500	2, $2,000	3, $2,300	4, $2,650	5, $2,950	6, $3,200
G. V. Electric	General Vehicle Co., Long Island City	½, $1,700	1, $2,100	2, $2,600	3½, $3,250		5, $3,700	
Urban	Kentucky Wagon Manufacturing Co., Louisville, Ky.	½,	1,	2,	3½.	(Prices on appli	cation)	
Victor	M. & P. Electric Vehicle Co., Detroit, Mich.	½, $1,550	1, $2,100.					
Walker	Walker Vehicle Co., Chicago, Ill.	½.	1, 1½.	2½.	3½.	(Prices on appli	cation)	
Ward	Ward Motor Vehicle Co., New York City	¾, $1,450	1½, $1,900	2½, $2,400			5 $2,950	
Waverley	The Waverley Co., Indianapolis, Ind.	½, $2,000	1, $2,400	2, $3,250	3½, $3,750		5, $4,500	

* Front wheel drive.

Scarcity of True Box Wood

IN the literature of the commercial woods of the world the word "box" appears frequently, applied oftentimes to woods that are widely distinct from each other. The word is usually employed with a prefix, even when the true box wood is meant, as Persian box, Russian box, Himalayan box, etc. In this article will be considered the wood of the box tree proper, the *Buxus sempervirens* of the botanists, which has been so generally imported into the United States and England as wood for the engraver's use. The German name of this tree is buxbaum; in French it is called buis; the Italian name is bosso, from which doubtless, its Latin name, *Buxus*, is derived; and in Persia it is known as Shanda laghune.

Its native home is Persia and the territory surrounding the Black and Caspian Seas, but it is in general cultivation in many parts of the world, and grows successfully as far north as 52 degrees latitude. While it grows in the temperate and more tropical climates, it is only for export in southern Europe and in parts of southern Asia. It is at present derived mainly from the forests of the Caucasus, Armenia, and the Caspian shores. The wood of the best qualities comes from the Baltic Sea forests and is shipped largely from the port of Poti. It is grown also in all parts of India, and in many districts flourishes in a wild state. It is but little planted and protected for its wood, but is largely grown and highly esteemed in Europe for ornamental and other useful purposes. To the gardener the box is a well-known, hardy evergreen tree or shrub, which seldom exceeds the height of from 12 to 15 feet in the United States, but in Turkey and Asia Minor it is sometimes found as high as 25 feet. The thickness of the trunk is often out of proportion to the height of the tree, because in full grown trees it varies from 6 to 9 inches in diameter near the ground.

Box wood is remarkably heavy (about 70 pounds per cubic foot), very hard, fine and straight-grained, takes a very high polish, and has a light yellow color. It is very liable to check in drying, and in order to prevent this the wood is placed in a dark cellar for from three to five years. At the end of this time the sapwood is removed with a hatchet and the heartwood again placed in a dark cool cellar or barn until wanted. For the best result the wood should be boiled for some time, and after it is dry, buried in dry sand until required.

The box wood has been in great demand already by the Greeks and Romans, and Theophrastus classed it with that of ebony on account of its usefulness and very fine grain. Pliny described box wood and said that it is as hard to burn as iron, and observed that it is totally unfit for charcoal. Both Virgil and Ovid stated that the wood was used very early for making musical instruments. With the advance of civilization box wood came into use for wood carving, and for this purpose it soon formed an important article of trade. It was also used extensively in England very early in cabinet making and inlaying, turnery, and a multitude of other purposes.

The use of box wood has been so very great that it is becoming scarce and consequently very costly. It is now so valuable that the trees are dug up by their roots and the latter are used for various articles of turnery. The root wood is very beautifully marbled or veined and the articles manufactured from it vary in value accordingly. The tree grows exceedingly slow, and the rate of consumption is far greater than the growth. No wood has yet been found to take the place of box for engraving, and for this the demand is great and the supply is limited. The want of the present day is a suitable substitute.

Mechanical Management

SO much has been said of late about scientific management in manufacturing establishments that it may be desirable to look ahead a little and endeavor to see just what departments of productive activity are really in line to be managed according to the methods thus advocated. In general, it seems as if the lines of work capable of such organization and conduct are those from which, in the course of a comparatively short time, the skilled mechanic may be almost wholly eliminated.

Repetitive processes, operations which may be described in instruction cards or planned out wholly in advance by some one other than the individual by whom they are to be executed, are the very ones from which the element of individual judgment may be almost entirely removed, and therefore are next in line to be turned over to an inanimate and almost entirely automatic machine. The things which the machine cannot do to advantage are those which are not performed twice alike, and into which the immediate and varying judgment of the man who is really doing the work must enter. Such work is becoming of less and less importance from the commercial point of view, and the real mechanic, according to the old-time standard, is almost to be classed with the artist, the man into whose work his own personality enters so largely as to make it impracticable for him to tell any one else how to do it as well.

When a piece of work demands the private judgment of the operator to any material extent, it is hardly adaptable to any system of intensified production, such as is desirable for the methods of modern scientific management.

It follows that one of the important things in connection with the introduction of such a plan lies in the systematization of the product itself, to render its manufacture practicable under the new conditions. If, however, such a study is given to the repetitive character of the product, it will be found, in nearly every instance, to lead to the introduction of such mechanical methods as to take practically all discretion out of the hands of the operative and convert him into a machine tender, his speed being determined by that of the machinery with which he is associated, and he himself becoming practically a part of those machines.

Such a condition of affairs has already been reached in some departments of industry, and there is every reason to believe that it will be extended. Its growth means a change in industrial conditions which will well bear examining, and it seems as if the present interest in scientific management is really only an intermediate and passing stage in a far deeper transformation in manufacturing conditions.

The kind of work which, if done by men, must be done in a mechanical manner, is the kind of work which should not be done by men at all; and it is for the advancement of the race to have it taken out of the hands of human beings and transferred to inanimate mechanism. This means that men must be given a higher and better kind of work to do, work which involves the use of their heads as well as their hands, and the men who have hitherto performed purely mechanical work qualify for the newer and higher class of activity. The Suez Canal was dug with human hands and wicker baskets; the Panama Canal is being excavated by the steam shovel, the hydraulic jet, and the dump car, under the guidance of men of intelligence and judgment.

When, therefore, any department of industry is studied with a view to the introduction of scientific management, it is suggested that the study be carried on to the next stage of technical progress without lingering at the transitory phase, and that a direct effort be made to arrange the product and the processes in such a manner as to permit the employment of a limited number of highly intelligent directors, and of such a number of machine tenders as may be necessary, relegating everything which can possibly be performed in a purely mechanical manner to a machine and not to a man.—*Cassier's Magazine.*

Preventing Mold on Books.—An effective way to prevent books from becoming musty and possibly moldy in moist weather is to place a few drops of oil of lavender and Canadian balsam in a back corner of each shelf. This will not injure the bindings of leather books as sulphur compounds do, but helps preserve the bindings. The two substances are easily obtained.

A Price List and Table of 1914 American Gasoline Pleasure Cars

A Ready Reference Table for the Prospective Automobile Purchaser

Compiled by C. Edward Palmer

THE composite price list of pleasure cars published in the Scientific American *Automobile Number of 1913 received such favorable comment at the time that it has been decided this year to publish a list on a much broader scale. Such lists are of great benefit to those who visit motor shows with the intention of buying a car. Every prospective automobile buyer must answer the old question: "What Cars Are Within My Price?" It is chiefly for the benefit of such prospective buyers that the compact information here presented has been prepared.*

The following table is self-explanatory except for the abbreviations used. In the fourth column the first figure indicates the number of cylinders; the second gives the rated horse-power. The letters refer to the type of body used on that particular chassis. Thus, r, *means roadster;* t, *means touring car;* l, *limousine;* c, *coupé;* ld, *landaulet;* p, *phaeton;* b, *berline;* s, *sedan.*

The table does not pretend to be absolutely complete. It does not include manufacturers whose output amounts only to a very few number of cars each year; nor does it include every car turned out by the manufacturers listed. Wherever further information as to other types is desired the manufacturers will furnish complete details, catalogues, and specifications on request.

Price.	Name of Car	Name and Address of Manufacturer	No. of Cylinders, Horse-power and Body Type
$450	Duryea	Duryea Motor Co., Saginaw, Mich	2, 14 buggy
475	Metz	Metz Co., Waltham, Mass	4, 22, r
495	Grant	Grant Motor Co., Detroit, Mich	4, 21, r
500	Ford	Ford Motor Co., Detroit, Mich	4, 20, r
550	Ford	Ford Motor Co., Detroit, Mich	4, 20, t
650	Duryea	Duryea Motor Co., Saginaw, Mich	2, 14, r
750	Chevrolet	Chevrolet Motor Co., Flint, Mich	4, 24, r
750	Comet	Continental Motors Corpn., Buffalo, N. Y	4, 25, r
750	Ford	Ford Motor Co., Detroit, Mich	4, 20, c
750	Maxwell	Maxwell M. C. C., Detroit, Mich	4, 25, t
750	Oriole	Columbia Electric Co., Knightstown, Ind	4, 20, r
750	Vulcan	Vulcan Mfg. Co., Painesville, O	4, 27, r
850	Detroiter	Briggs-Detroiter Co., Detroit, Mich	4, 25, t
850	Read	Read M. C. Co., Detroit, Mich	4, 33, t
850	Vulcan	Vulcan Mfg. Co., Painesville, O	4, 27, t
875	Chevrolet	Chevrolet Motor Co., Flint, Mich	4, 24, t
885	Studebaker	Studebaker Corp. of America, Detroit, Mich	4, 25, t

"Here are the General Offices and Works of The Electric Storage Battery Co.—the largest storage battery plant in the country."

POWER FOR STARTING AUTOMOBILE ENGINES AND ELECTRIC LIGHTING

To start an automobile engine requires power—lots of it—especially in cold weather.

The real reason why electric starting and lighting apparatus has been so wonderfully reliable and is being almost universally adopted is because the storage battery has proved itself to be the most useful and efficient reservoir of energy for this purpose.

To crank an engine, a storage battery must develop from one-half to one horse power for a few seconds or minutes.

To light the lamps, it must develop about one-fifteenth horse-power for 8 to 15 hours without recharging.

It must receive and utilize the energy delivered it by the generator without waste. It must do its work, month in and month out, at temperatures ranging from below zero to 100° F.—instantly, automatically and cheerfully. It must demand (because it will receive) less care and attention than engine, gear box or any other vital part of the car.

THE "Exide" STARTING AND LIGHTING BATTERY

has been designed and constructed with a thorough knowledge of the varied character of the work it must do. It is made by a company that has had 25 years of experience in storage battery manufacture, covering every field in which storage batteries are used.

This company manufactures and has manufactured more storage batteries than all other battery makers put together. Two out of every three automobiles using electric self-starting and lighting apparatus are equipped with an "Exide" Battery. There are over 100,000 "Exide' Batteries now in service used for starting, lighting or ignition.

For electric vehicle propulsion "Exide" Batteries have for years been the standard among nearly all electric vehicle manufacturers and are to-day used by the largest electric vehicle owners. The large electric lighting companies use "Exide" Batteries as *reservoirs* of current for use in emergencies. They are used by the U. S. Government in 20 submarines, for firing large guns, for light-ships, for electric vehicles and for wireless apparatus. In New York City 182 storage battery street cars are propelled by "Exide" Batteries.

Unless you are a trained engineer, you cannot safely judge of the quality of a storage battery. Your best protection is to select a battery that is manufactured by a company having the necessary experience and facilities and a battery that has been approved by large battery users—those who are experts.

Your car is or will no doubt be equipped for electric self-starting and lighting.

REMEMBER, THE STORAGE BATTERY IS THE "HEART" OF THE SYSTEM.

You can be absolutely assured of dependable every-day service by using the "Exide" Battery. Insist upon the "Exide". Your dealer can secure it if *you* insist.

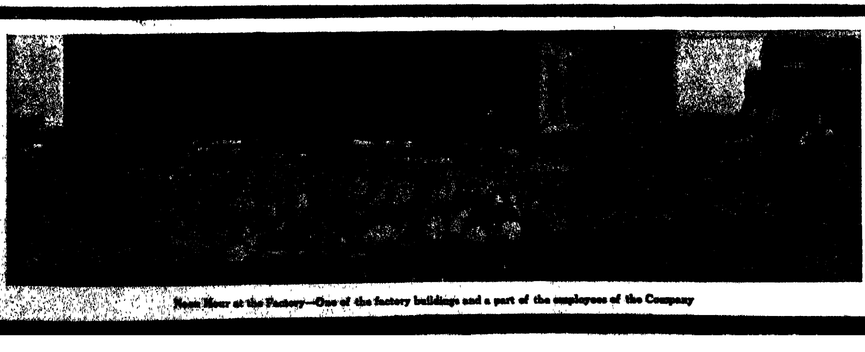
THE ELECTRIC STORAGE BATTERY CO.

Manufacturer of
The "Chloride Accumulator", The "Tudor Accumulator",
The "Exide", "Hycap-Exide", "Thin-Exide" and "Ironclad-Exide" Batteries

PHILADELPHIA, PA.
1888-1914

New York, Boston, Chicago, Denver, San Francisco, Seattle
St. Louis, Cleveland, Atlanta, Detroit, Los Angeles, Portland, Ore., Toronto

886 "Exide" Distributors
9 "Exide" Depots
"Exide" Inspection Corps



Noon Hour at the Factory—One of the factory buildings and a part of the employees of the Company

A Price List and Table of 1914 American Gasoline Pleasure Cars

(Concluded from page 26.)

Retrospect of the Year 1913

(Concluded from page 7.)

structions laid upon this specimen by conflicting authorities. At present all evidence seems to be in favor of the view that a race of man somewhat similar to modern civilized man has existed for a very long period of time, and was coeval with the very low Heidelberg and similar types. Reports of the experimental solar power plant in Egypt are very encouraging, and we shall look with interest for further developments in this direction. Molecular physics continues to be one of the most actively developing fields of research. We have come to look upon atomic weight as not necessarily defining one single element—several elements may have the same, or very nearly the same atomic weights, according to the point of view developed by Prof. Soddy. Dr Hevesy, speaking at the British Association on "Radioactive Elements as Indicators in Physics and Chemistry," pointed out the extreme delicacy of radioactive methods of observation: "By means of an α ray electroscope it is possible to measure exactly as small a quantity as 10^{-11} grammes of radioactive substance having a half-period of one hour." By the aid of such methods 10^{-6} milligrammes of lead is quantitatively determinable. Sir Oliver Lodge's address attracted considerable popular attention, mainly on account of his reference to spiritualistic phenomena. It can hardly be said to have brought to light any strikingly new facts or viewpoints. Wireless telegraphy in the service of meteorology and allied sciences has won a triumph in the establishment of radio-telegraphic connection between the Eiffel Tower, Paris, and the radio tower at Arlington, Va., near Washington, D. C. In the field of eugenics the camp has recently suffered a somewhat sharp scission. The general of the American forces, Prof. Davenport, has advocated the doctrine "let the weak wed the strong," as opposed to the Pearsonian doctrine "let the strong wed the strong." Davenport contends that the doctrine of the English school is theoretically correct, but practically incapable of application, as it would restrict marriages to a point suicidal to the race. With all these discussions as to what eugenic practice ought to be, one is led to wonder what actual practice is. Has the preaching of the eugenist had any measurable effect? Perhaps this can be claimed for it, that it has influenced legislation in favor of restricting the offspring of defectives. The Pasteur Institute has just celebrated its twenty-fifth anniversary—and what institution can show a record of greater success and usefulness for the same period than this great life-saving station? Two records made during the year seem to deserve special mention. The highest altitude reached by a sounding balloon has been raised from 20.15 to 23.4 miles. Mount McKinley has been scaled by Archdeacon Hudson Stuck and his party.

Obituary.

In noting briefly—as needs we must—the death roll of the past year, we mention first the death of John Fritz, a pioneer ironmaster, and one of the most distinguished manufacturers in that iron and steel industry in which this country leads the world. Fritz was the typical successful American inventor. Born of German and Scotch parents in 1822, he picked up his practical education while working on a farm. In 1844, as an apprentice to a mill for rolling bar iron, he came into touch with the great industry in which he was to become a leading figure. When the Bessemer process was introduced into this country Fritz, with Holley and Jones, applied his genius to the improvement of the process. By taking up the manufacture of armor plate, he assisted in the re-creation of our navy. The universities owe much to his influence and assistance, and he was honored by the engineering societies, both of this country and Great Britain. He founded the John Fritz Gold Medal, and his personal qualities made him endeared to the whole engineering fraternity.

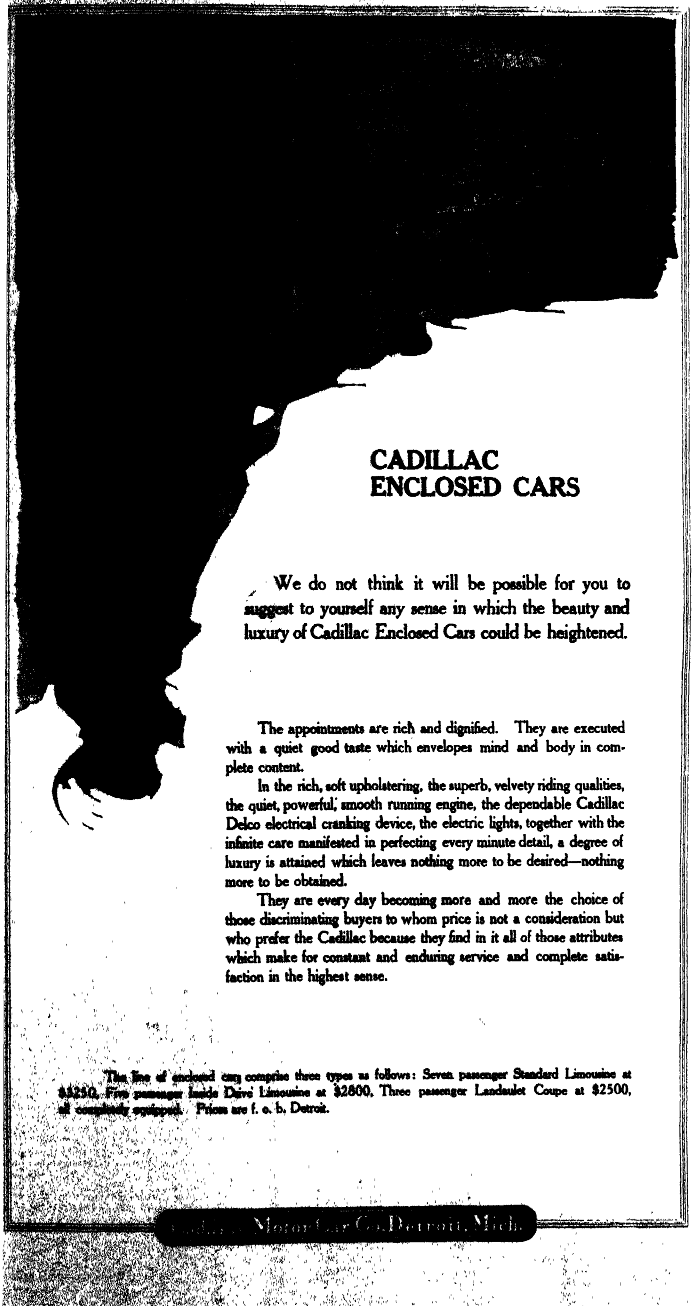
In Sir William White the world lost its most distinguished and widely known naval architect. For many years he was the Director of Naval Construction and Assistant Controller of the Royal Navy; and no architect has left so strong an imprint upon warship design. As consulting architect for the "Mauretania" and "Lusitania" he had much to do with the design of these famous vessels. Knighthood was but one of many distinguished honors conferred upon Sir William during his long and exceedingly active life.

In Gustav de Laval, the technical world lost one of its most brilliant inventors. It has been estimated that the cream separator and milk tester devised by him saved millions of dollars to the world's dairy interests alone. He was a pioneer in the construction of the steam turbine. Like Fritz and White, he combined with his inventive and constructive ability the advantages of great worth of character.

Another deplorable loss of the year was the untimely death of Rudolph Diesel, the inventor of the famous oil engine which bears his name. His fame may well rest upon the results already achieved with his invention. What the future has in store can be only surmised; but it is certain that the Diesel engine will take rank with the Parsons turbine as marking one of the epochs in that development of prime movers which opened with the work of James Watt.

The passing of Alfred Russel Wallace reminded those who knew, and informed the great multitude who did not know, that this distinguished scientist was the co-founder with Darwin of the modern theory of evolution. Strange indeed it was that two men at opposite ends of the earth should have worked out, unknown to each other, an identical solution of the problem of the genesis of species. But so it was. Wallace was far from being a narrow pedant, wedded to his specialty to the exclusion of other matters; for he was a man of broad interests and deep sympathy. He leaves his luminous writings as a monument to his industry and his long sustained devotion to the advancement of truth.

The death of Lieut. Col. C. D. Gaillard, after his return from the Panama Canal in broken health, was recognized as one more instance of the sacrifice of self to duty, of which there are so many brilliant examples among the naval and military men of this country. To Col. Galliard, who, for six years, had charge of the excavation of the Culebra cut, was due the wonderful organization which enabled that stupendous work to be done with the speed and economy which marked its progress. Somewhere in the great cut, a grateful country should erect a fitting monument to the technical skill and personal devotion of this distinguished army engineer.



CADILLAC ENCLOSED CARS

We do not think it will be possible for you to suggest to yourself any sense in which the beauty and luxury of Cadillac Enclosed Cars could be heightened.

The appointments are rich and dignified. They are executed with a quiet good taste which envelopes mind and body in complete content.

In the rich, soft upholstering, the superb, velvety riding qualities, the quiet, powerful, smooth running engine, the dependable Cadillac Delco electrical cranking device, the electric lights, together with the infinite care manifested in perfecting every minute detail, a degree of luxury is attained which leaves nothing more to be desired—nothing more to be obtained.

They are every day becoming more and more the choice of those discriminating buyers to whom price is not a consideration but who prefer the Cadillac because they find in it all of those attributes which make for constant and enduring service and complete satisfaction in the highest sense.

The line of enclosed cars comprise three types as follows: Seven passenger Standard Limousine at $3250, Five passenger Inside Drive Limousine at $2800, Three passenger Landaulet Coupe at $2500, all completely equipped. Prices are f. o. b. Detroit.

Cadillac Motor Car Co. Detroit, Mich.

How British authorities regard the Cadillac two-speed axle

"The Autocar" says

"It would be difficult to outline an ideal car without this feature."

In conjunction with the recent award of the Dewar Trophy to the Cadillac—the second time within five years that this treasured mark of merit has been bestowed on the Cadillac—it is interesting to note how British automobile authorities regard the Cadillac's two-speed direct drive axle.

This axle was even more of an innovation in Great Britain and Europe than in the United States; but it is very evident, from published comments, that it has found immense favor among those qualified to speak with authority on the subject of motor car advancement

The Autocar, one of the leading motor publications of England, declaring it would be difficult to outline an ideal car that did not incorporate this feature, says:

"When the Cadillac system of combining ignition, lighting and engine starting in one electrical system was introduced two years ago, it was very properly regarded as a bold step; experience has shown it to be as successful as it was bold Today the Cadillac designers have made another innovation, which, personally, we regard as even a greater improvement than the very important one of two years ago As a basis, they have taken the old idea of two pairs of bevel gears, either pair working alternately and giving the car two different gear ratios; but the way in which the Cadillac designers have adopted it is new, and the working results are not merely satisfactory; they are so good that they mark a distinct forward step toward the long sought ideal of direct and noiseless gears on all speeds.

"We have had a good bit of experience with high geared fourth speeds, the direct drive on the third speed and the indirect on the fourth. We found these indirect fourths pleasant to use, but the moment we put in the high indirect fourth, the gear box began to make its working apparent Now, with the Cadillac one gets all the advantages of the high fourth, but without the noise, it simply, as it were, calms down on the engine without any counter balancing noise or other objection

"After once experiencing the delight of two direct and noiseless drives one feels that it is difficult to outline an ideal car which does not contain this feature, and we feel fairly safe in asserting that the Cadillac successful reintroduction of an old idea will be followed by other makers"

"The Motor," another British technical authority, comments

"We have always held the Cadillac in the highest esteem, and admired it as a criterional example of high-grade American construction. The charm of the dual drive to the rear axle is compelling and entrancing, and as one merely touches the little lever at the side and, on depressing and allowing the clutch to rise, finds a higher direct drive available, wonderment is aroused as to the undoubtedly simple manner in which so great an advantage has been brought about.

"The luxury of driving a touring car at 20 or 25 miles an hour with a direct drive and final gear ratio of 2.5 to 1 is quite a new fascination."

From "Horseless Age."

"It seems at least possible that the two speed axle may confer upon the four-cylinder car sufficient flexibility and accelerative ability, without recourse to noisy geared speeds, to satisfy the public demand for these qualities, and, if this should prove to be the case, the demand for six-cylinder cars, with their somewhat more costly, more bulky, more complicated and less economical motors, might be materially reduced. It can hardly be doubted that the advent of the double-direct drive is one of the most important happenings of recent years in the automobile industry."

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

LOW CUT SHOE ATTACHMENT.—W. E. BUNKER, Natick, Mass. This invention relates to "pumps" or low cut shoes, and provides an attachment to prevent the shoe from spreading or gaping in the movements of walking. The invention provides a stiffener whose use will not result in discomfort at the back of the heel, and the stiffener may be readily attached to any low cut shoe.

WARDROBE TRUNK.—M. CHERRY, JR., 226 5th Ave., Larchmont Manor, N. Y. The object of the invention is to provide a simple, strong and compact carriage, which will accommodate hangers, extending through the entire width of the trunk and will prevent any displacement of the hangers when engaged in the same carriage frame.

LOCKING DEVICE FOR CLASPS.—M. SCHIFF, care of Samuel D. Schwitzer, 309 Broadway, N. Y., N. Y. This device is for use as the clasp of a bracelet, necklace or other article of jewelry, and is arranged to prevent accidental opening of the clasp, to be inconspicuous and avoid marring of the appearance of the article, and to present no undesirable projection on the surface of the article.

Electrical Devices.

ELECTRIC FIRE ALARM.—F. RICORDS and M. LEWRY, care of the latter, 573 Washington Ave., Brooklyn, N. Y. This alarm relates to alarms which may be installed in a building with an indicator on each floor having a bell and a switch, with electrical connections for ringing all the bells and for lighting a certain lamp on each floor when an alarm is given, by closing one of the switches.

ELECTRIC-MOTOR DRIVING UNIT.—M. TAIGMAN, 239 Wooster St., New York, N. Y. The invention pertains to improvements in individual motor equipments for power driven machines, and more particularly to equipments to be installed for operating bench machines and controlled by means of foot operated devices.

Of Interest to Farmers.

COMBINATION CUSHIONED FLAT AND FILLER.—W. MERKER, 22 Covert St., Brooklyn, N. Y. The purpose in this case is to provide a cushioned flat and filler arranged to reduce breakage of eggs while in the egg carrier to a minimum and to protect the members forming the filler from being bent or broken, thus insuring long life of the egg carrier and permitting its re-use for a long period.

CORN PLANTER.—E. J. OGDEN, 502½ N. Sixth St., Springfield, Ill. The invention more particularly is directed to an improved means for actuating the seed dropping mechanism whereby the seed may be deposited at certain intervals in the ground. The principal object is to provide a planter having efficient means for actuating the seed dropping mechanism.

IRRIGATING APPARATUS.—G. S. WILLIAMSON, Elk Grove, Cal. The purpose here is to supply an apparatus adapted for use in sprinkling large fields and the like, the liquid employed in sprinkling being adapted to operate the sprinkling mechanism. For this, use is made of a track pipe line provided with valves, and a carriage mounted to operate over the track pipe line and moved by the liquid taken from the track pipe line through the said valves, and transmitted to operating means on the carriage after which the said liquid is ejected from a sprinkler mounted on the carriage.

IRRIGATING APPARATUS.

Of General Interest.

FORM FOR CEMENT CISTERNS.—G. A. WATKINS, Columbus, Ohio. This invention relates to a form for cement cisterns and is particularly devised to produce a knock-down form to attain such result in a manner to permit of the removal of independent sections constituting the form without in any way decreasing the security of the remaining parts in their proper position.

STREAM DEFLECTOR.—W. H. DEAN, P. O. Box 58, Morningside, Sioux City, Iowa. The inventor provides a deflector more especially designed for use in rivers and other waterways, and arranged to divert or deflect the current of the waterway with a view to prevent the same cutting into the bank, to maintain a channel along a proper predetermined line and to insure the formation of a permanent shore line.

MILK BOTTLE HOLDER.—J. J. DUNN, 4580 Park Ave., New York, N. Y. This invention provides a holder locked in holding position only when having contained therein a capped or filled bottle, to avoid interference or meddling; provides a holder mountable upon the frame of a door or window, which may be released only by opening the door or window; provides a holder temporarily mounted beside a door or window which may be removed during the intervals between the delivery of the bottles containing the milk; and provides a holder to operate in conjunction with a door or window sill or other rest, which when locked is held in position by the adjacent door or window.

PROPELLER.—H. D. F. BAGLEY, care of E. Brimfield Hampden Co., Holland, Mass. This inventor provides a propeller having a maximum of efficiency in developing speed from a given power, and provides a form and arrangement of blades that will present a maximum of surface to the water at the hub and yet minimize the cavitation.

BANJO, DRUM, OR SIMILAR MUSICAL INSTRUMENT.—C. HABERMANN, care of Oscar Schmidt, 87 Ferry St., Jersey City, N. J. This invention provides improvements in banjos, drums, or similar musical instruments, whereby a sharp, clear and melodious tone is produced, and the construction of the means for drawing and holding the tightening ring in place is simplified and a finer appearance is given to the instrument.

BOTTLE CLOSURE.—H. V. PICK, care of Bernard Noonan, 835 Columbus Ave., N. Y., N. Y. This bottle closure is especially adapted for use with the form of bottles having a long neck as a handle portion. It is also adapted to snugly fit about the mouth of the bottle, so as to prevent the entrance of dirt, dust or any foreign material to the liquid in the bottle.

DEVICE FOR APPLYING SUBSTANCES TO TREES, SHRUBS AND VINES.—W. R. KLECKNER, Cowell, Cal. By means of this device an insecticide or other substance may be so applied to a tree, shrub, or vine, as to enable the sap to readily take up such substance. It will prevent injury to the growths named, and will prevent leakage and waste of the substance to be applied thereto.

Heating and Lighting.

PIPE SUPPORT.—W. B. GRAY, 1327 South 22nd St., Louisville, Ky. This is an improvement in traveling supports for pipes, and the aim is to provide a safe and simple device for supporting heating and power pipes, wherein means is provided for permitting the expansion and contraction of the pipes without injury to the pipe or to the support. Mr. Gray has invented another device for supporting heating and power pipes wherein means is provided for permitting the expansion and contraction of the pipes without injury to the said pipes or to the support.

FILAMENT LAMP.—M. SIDON, 616 W. 182nd St., New York, N. Y. This invention relates generally to filament lamps and more particularly it involves a lamp of this type in which the bulb is made of a plurality of parts adapted to fit closely together whereby the proper vacuum within the bulb may be secured.

AUTOMATIC FURNACE DAMPER.—A. W. ARNOLD, Goshen, Ind. This improvement relates to dampers or draft governors which are designed to operate automatically under the influence of the draft itself to maintain a substantially uniform combustion of fuel, in accordance with the conditions for which the devices may be adjusted.

VALVE FOR GAS BURNERS.—E. S. ALLEN, 517 W. 184th St., New York, N. Y. The more particular purpose of the inventor is to produce an article having a number of its movable parts located within a sleeve forming a part of the burner and rendered detachable for the purpose of facilitating the removal and replacement of said movable parts.

Household Utilities.

FLY PAPER HOLDER.—J. R. SMITH, Stella, Mo. This invention relates to insecticides, and has particular reference to a means for holding ordinary sticky fly paper to prevent the same from being exposed in an unsightly and unsanitary manner, and at the same time will be held from being blown about by puffs of wind or the like.

CURTAIN FIXTURE.—H. REUBEL, 107 E. 17th St., Manhattan, N. Y., N. Y. This fixture is arranged to permit of conveniently placing the curtain rod in position on the supporting brackets to securely hold the curtain rod in place on the brackets, and to allow of placing the fixture directly under an overhanging or projecting molding or the like.

Machines and Mechanical Devices.

TICKET DEPOSIT BOX.—J. ANDERSON, 408 Grand View Ave., Ridgewood, N. Y. This invention provides means for canceling, exhibiting and depositing tickets mechanically and outside of the control of the attendant; provides for preventing the extracting of tickets from the deposit box after being placed therein, and provides a mechanism for operating the canceling and depositing devices which is simple, efficient and durable in construction.

CONTROL OF BRUSHES.—M. VANDAL, 8 Rue St. Augustin, Paris, France. The invention pertains to improvements in control of brushes whereby to communicate to two sets of brushes, having each one or more brushes, both a reciprocating and a circular motion in the brushing plane. The combination of these motions is for the purpose of distributing any material, such as color for instance, equally on any surface plane or substantially so.

EXPANSION LIFT.—M. L. [illegible], [illegible] Fairmont Ave., Jersey City, N. J. This inventor provides a mechanism having a pivoted base to permit a lateral swing of said mechanism thereon; provides a thrust member for said mechanism, pivotally mounted thereon to rock in a plane perpendicular to the plane of rotation of said base; and provides a mechanism having terminal thrust members and a flexible expansion member to connect the thrust members, and pivotally connected with these members to permit disposition thereof in angularly disposed planes.

SAFETY GEARING FOR DRILLS.—J. O. FOSTER, Peculiar, Mo. It is sought in this invention to provide cushioning mechanism interposed between relating movable parts of the winding mechanism, and so arranged that when the drill is dropped, the shock upon the gearing is cushioned and the consequent damages to the gearing are reduced to a minimum.

Prime Movers and Their Accessories.

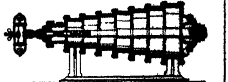
JOINTING APPARATUS FOR BOILER TUBES.—S. A. DUGAN, [illegible], Canal Zone, Panama. The device secured by this patent is for joining the tubes of steam boilers to the tube sheets. The inventor produces an annular depression in the sheet to receive the tube, and he employs for the purpose a hollow shaft having radially movable rollers which are gradually expanded by a tapered spindle, the spindle shank being threaded and receiving a nut fitting in a recess in the shaft.

INTERNAL COMBUSTION ENGINE.—F. D. CALKINS and A. C. JOHNSON, Sunnyvale, Cal. The invention has for its purpose to provide means for controlling the admission and exhaust of the motive fluid, wherein a continuously rotating valve having a large bearing surface is provided separated from the explosion chamber of the engine by a water jacket, and arranged to automatically compensate for wear. The inventors have patented another internal combustion engine which provides on an engine a rotating valve having a large wearing surface and separated from the explosion chamber in order to prevent heating and deposits of carbon, and wherein means is provided for automatically compensating for the wear on the valve.

Prime Movers and Their Accessories.

ROTARY PUMP.—A. F. FORD, 1165 Pine St., Walla Walla, Wash. This invention has reference to improvements in rotary pumps, and has for an object the provision of an improved structure in which the pumping apparatus may be arranged to operate as a horizontal pump or a vertical pump.

ROTARY ENGINE.—G. E. CALLAWAY, Jonesboro, La. Address J. M. Beadley, secretary. This engine provides a series of casings successively increasing in diameter, and the steam is used expansively in each casing in succession. The shaft extending through the several casings carries rotors of elliptical form which coact with vanes and abutments against which the steam acts, and special governor elements are associated with the engine.



ROTARY ENGINE.

Railways and Their Accessories.

LOCOMOTIVE AXLE BEARING.—W. C. STEPHENSON, Rocky Mount, N. C. Journal blocks or bearings of locomotives are commonly inserted from below in slots provided in the frame and secured by wedges called "wedge-bolts." When the last break or require removal or replacement, it is necessary to first remove the horizontal bar, or so-called "binder," by which the wedge-bolt is supported. The object here is to provide an improvement whereby the removal of the wedge-bolt can be very easily and quickly effected.

Pertaining to Recreation.

PIN SETTER FOR BOWLING ALLEYS.—R. SCHLOSSBERG, 1007 Metropolitan Ave., Brooklyn, N. Y. The invention refers more particularly to means for centering the tenpins, which means comprise a plate or platform provided with openings for the pins and means for actuating the plate. The pin setter indicates to the players that the pins are set in the proper places.

Pertaining to Vehicles.

HORSE DETACHER.—R. [illegible] and W. H. CORDER, North Carrollton, Miss. An object of this invention is to provide means whereby a horse which is harnessed to a vehicle may be liberated therefrom, such means consisting in a device for detaching the traces, the hold-back, and the bellybands, thus permitting the horse to emerge from between the shafts clear of the vehicle.

SIGN AND INDICATOR.—F. [illegible], care of V. Piccio, 1015 Franklin St., Tampa, Fla. [illegible]

[illegible] STREET CLEANER'S CART.—[illegible], 406 So. Warren St., Trenton, N. J. In this patent use is made of a cart body having means to detachably hold a bag or sack, and an endless chain is mounted within the body of the cart and carries buckets [illegible]

STREET CLEANER'S CART.

adapted to dump the material into the sack, there being a bevel pan and appurtenances at an opening provided in the body at the side opposite the sack whereby the street cleaner may sweep the material in the street into a carrier bucket presented at the opening. Means are provided to lock the chain with an empty bucket disposed at the receiving opening.

DEMOUNTABLE RIM.—L. A. GORDON, 168 Barclay St., Fall River, Mass. The rim is especially for use in wheels having pneumatic tires, for permitting the rim which directly supports the tire to be demounted from the wheel, in order to facilitate the removal of the tire from engagement with the rim. Means are provided whereby the rim may be mounted on wheels having ordinary rims of the clincher or quickly separable type, without requiring changes in the rim itself.

Pertaining to Vehicles.

AUTOMOBILE VEIL.—M. SALZ, 30 W. 32nd St., New York, N. Y. This veil is designed especially for ladies' use, and the object of the invention is to provide a veil designed more especially for use when automobiling or the like, to protect the wearer from excessive air currents and dust, thus permitting the taking of a trip with increased comfort and enjoyment.

HARNESS ATTACHMENT FOR SECURING NETS AND BLANKETS.—F. H. MCCORMICK, 19 Charles St., Hillsdale, Mich. The device comprises a bucklelike frame, a prong or tongue pivoted thereto, and a spring for holding said prong in either of two positions, to wit, folded as when engaged with net or blanket, or extended laterally as when serving as a rein-guard.

AUTOMOBILE JACK.—J. DE H. BUNN, Address Dr. Philip R. Koons, 33 West Main St., Mechanicsburg, Pa. The purpose here is to provide a device by means of which an automobile or like vehicle may be lifted clear of the ground or other supporting surface and held in such position as long as necessary, and wherein the device is capable of adjustment for different heights.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

DELCO

ELECTRIC CRANKING LIGHTING IGNITION

A Delco Equipped Car Has Won the World's Greatest Automobile Honors

An American motor car equipped with the Delco Electric Cranking, Lighting and Ignition System has been awarded the famous Dewar Trophy by the Royal Automobile Club of England.

The Delco system itself did not win this highly prized trophy, but it was so severely tested in the trials, and the record it made was so remarkable, that some facts regarding it are bound to be of interest to motor car owners.

The trials that determined the award of the Dewar Trophy involved driving 1,000 miles over all sorts of roads at an average speed of 19.5 miles an hour. *This is somewhat misleading, however, as an exceptionally high rear axle gear ratio was used throughout the trial and the actual speed at which the electric generator was driven was the equivalent of only 13.2 miles per hour with a standard rear axle.*

During the entire trial, which lasted 66 hours and 17 minutes, or more than three days and two nights, all electric lights were burned continuously.

Actual driving time, however, was only 51 hours. For over 15 hours all lamps were burned, while no current was being generated.

The cranking device was used 130 times; an average of once every 30 minutes during the entire 66 hours. And at the end of the trial the batteries were still sufficiently charged to crank the engine 1000 compressions and burn the side, tail and speedometer lights 20 additional hours.

In other words, in spite of the heavy and continuous drain on the batteries for over 66 hours, while the generator was being run at unusually low speed for only 51 hours, the battery was still well charged at the end of the trial.

Another very gratifying phase of the Committee's report is found in the statement that—"IT WAS OBSERVED AND NOTED THAT THE IGNITION WAS PERFECT THROUGHOUT THE TRIAL."

And yet while this entire performance of the Delco equipment is very wonderful, it is not at all surprising to drivers of Delco equipped cars.

More than 75,000 automobile owners are duplicating, day after day, in their own driving, the experiences of the Royal Automobile Club Committee.

DO YOU KNOW:—That the President of the United States has "ELECTRENE" Fire Extinguishers on his motor cars?

DO YOU KNOW:—That the

"ELECTRENE"

FIRE EXTINGUISHER

was awarded the GOLD MEDAL and DIPLOMA of MERIT at the INTERNATIONAL EXPOSITION of SAFETY and SANITATION, held in the Grand Central Palace, New York City, December 11-20, 1913?

DO YOU KNOW:—That the "ELECTRENE" Fire Extinguisher is STANDARD in the NEW YORK FIRE DEPARTMENT?

DO YOU KNOW—That the BROOKLYN RAPID TRANSIT CO. has placed One Thousand "ELECTRENE" Fire Extinguishers on its electric cars recently?

DO YOU KNOW—That the great hotels, the Waldorf-Astoria and the new Biltmore, have placed Three Hundred "ELECTRENE" Fire Extinguishers in their equipment?

THERE IS A REASON—IT IS THIS. Discriminating buyers who consider MERIT and believe in the "PROTECTION FIRST" policy—tell us that "ELECTRENE" is in a class by itself, when it comes to a question of Quality-efficiency and reliability.

We know this to be true, and are ready to back up this assertion in open competition with any extinguisher on the market, of the same type as "ELECTRENE."

Send for circulars.

Notes for Inventors

Housing the Bed in the Ceiling.—Theodore H. Sorlein, Granite Falls, Minn., has secured a patent, No. 1,069,585, for a bed which when not in use can be moved up into an opening or recess in the ceiling and then a false ceiling plate can be moved to obscure the bed from view. The English novelist H. G. Wells some years ago suggested that bed-making could be simplified by hoisting the bedclothes on strings between ceiling and floor and by dropping them into position again when bedtime comes.

Three Patents Relating to Steel Production.—James Churchward of Mt. Vernon, N. Y., has secured three patents, one, No. 1,069,318, being for an optical pyrometer adapted to be used in measuring of glowing bodies and by which the temperature may be measured by direct observation of the glowing body, by passing the rays through a medium having an adjustable opacity and thereby eliminating all rays except those representing a certain shade whereby the temperature may be determined. A second patent, No. 1,069,387, relates to a steel process and an article, the process seeming to produce a fibrous structure in steel and compositions of steel. The third patent, No. 1,069,601, provides a rotatable furnace of special construction described as fitted to secure homogeneity in molten material and especially metallic mixtures.

A Number of Peter Cooper Hewitt Patents.—Peter Cooper Hewitt of New York, assignor to Cooper Hewitt Electric Company of Hoboken, has secured patents No. 1,064,685 for electric lighting apparatus, No. 1,064,686 for gas or vapor electric apparatus, No. 1,064,687 and No. 1,064,689 for vapor electric devices, No. 1,064,688 for electric lighting apparatus, No. 1,064,690 for automatic starting device for vapor lamps, and No. 1,064,691 for system of electrical distribution.

United States Patents to Foreigners.—hen we stop and consider the large number of patents of the United States issued to residents of foreign countries, we are surprised, and gratified that foreign residents appreciate the benefits and take advantage of the opportunity to secure patent protection in this country to such great extent. In a recent weekly issue of patents the total number of patents issued to residents of the United States was 442 while 95 patents were issued to residents of foreign countries, or more than twenty per cent of the number issued to residents.

Maturing Immature Cotton Bolls.—John Ellwood Lee of Conshohocken, Pa., assignor to John B. Hall of Philadelphia, has patented, No. 1,073,914, an apparatus for maturing immature, unopened or frost bitten cotton bolls, in which a moisture extracting chamber has an endless apron to receive the bolls and means for ejecting steam upon the bolls and for regulating the temperature of the moisture extracting chamber.

A High Combustible for Explosive Engines.—In a patent, No. 1,073,233, to Rudolf Hense, Charlottenburg, Germany, there is presented a process for obtaining a combustible of high value in which light hydrocarbons are added to heavy hydrocarbons and distilled at a high temperature and to the product caustic potash is mixed and the mixture settled. The settlement is then taken off and to the resulting mixture is added rosin substances as colophony and compounds of the nitro group as picric acid after which the mixture is settled, the liquid drawn off and purified and cleared by fractional distillation.

A Bookbinding and Covering Machine.—In patent No. 1,073,324 to Alfred Bredenberg of Champlain, N. Y., assignor of one half to the Sheridan Iron Works of New York and one-half to T. W. and C. B. Sheridan Co. of New York, is shown a bookbinding and covering machine having an endless carrier together with mechanisms for performing successively upon the book carried by the carrier various operations involved in binding and covering with such mechanisms arranged in series, part along one stretch and part along another stretch of the carrier.

LEGAL NOTICES

PATENTS

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their Inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty-five years ago.

All patents secured through us are described without cost to patentee in the Scientific American.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. *In every case it is necessary to give the number of the inquiry.* Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & Co., Inc.

Inquiry No. 9338. Wanted the name and address of patentees who desire to dispose of their patent rights in Silo Doors; also names of manufacturers of the same.

Inquiry No. 9339. Wanted names and addresses of purchasers of Uranium and Vanadium.

Inquiry No. 9340. Wanted the name and address of manufacturers of knock-down barrels, staves, hoops and heads which may readily be assembled.

Inquiry No. 9341. Wanted, mail order article. A man with long experience in the newspaper and advertising field desires to get in touch with the inventor or manufacturer of some quick-selling article, with the idea of inaugurating a Mail Order business to mutual profit.

Inquiry No. 9342. Wanted, a machine to cut No. 12 wire in 2½ inch lengths and sharpen both ends similar to tack points. One operation preferred.

Inquiry No. 9343. Wanted the name and address of manufacturers of machines for grinding the peel of oranges and grapefruit.

Inquiry No. 9344. Wanted name and address of manufacturers of patent articles of merit suitable for mail order distribution.

Inquiry No. 9345. Wanted name and address of manufacturers of Oxy-Acetylene Cutting and Welding Torch; also an easy opening can suitable for shoe polish.

Inquiry No. 9346. Wanted the name and address of [illegible] manufacturers, [illegible] and other machinery pertaining to cigar manufacturing and cigar banding machines.

Inquiry No. 9347. Wanted the name and address of an industrial school where [illegible] is taught in all its branches.

Inquiry No. 9348. Wanted the name and address of manufacturers having [illegible] with a view to obtaining exclusive territory for a house to house canvass.

Inquiry No. 9349. Wanted the names and addresses of the makers of machinery for making [illegible] Tonic, also a machine for [illegible] and machines for applying [illegible].

Maxwell 25/4 $750

The Pioneer of the Past—and of the Future

The Oldest, and yet the newest car in this Automobile Show is the Maxwell "25."

No name dates farther back in this industry—and yet if you look where the crowd blocks the aisle, you'll agree that visitors consider the latest Maxwell—the "25-4"—the newest of them all.

To say this $750 car is the "sensation" of the 1914 Show, would be trite—tho true. It is more than that.

It is Revolutionary.

Revolutionary, because never before has it been possible to obtain a car of such size, such capacity, such power, such performance and of such quality throughout, as you will see in this Maxwell "25" at the price—$750 fully equipped.

Revolutionary, too, because maintenance cost has been reduced to the minimum, by putting in this car the best steels known to science—thus making it light, yet practically indestructible. So you can now not only afford to buy, but to keep, an automobile.

We call it an engineering triumph. And you'll agree we are justified when you recall that for years, hundreds of thousands have been looking, hoping, waiting, for such a car at the price.

We say this car is the Oldest car in the Show—because more years of experience; more combined engineering skill; more know-how have gone into it than ever went into any other automobile at the price.

And, backing up that experience; that skill; that know-how; is as much money as ever backed an automobile concern.

Add to this, honesty of purpose, pride, and a desire to make good and to deserve well at the hands of every owner—and you have the elements that combined have produced this car that is the wonder of the Show—that blocks the aisle in front of the exhibit and thereby is proclaimed the Newest as well as the Oldest car in the Show. The Pioneer of the past—and of the future—the Maxwell "25."

ARE YOU "HITTING IT OFF RIGHT" WITH YOUR CIGAR?

WE ask because we have had rather a big success in making cigars that "hit it off right" with the extra-critical smoker.

You've heard of **WAITT & BOND** since you first became interested in smokes,—and your daddy knew us before that. So that's enough by way of introduction.

Now we're talking to you from our wonderful, new cigar factory,—the big, white, clean-as-sunshine show-place of cigardom.

Wabon Panetela

10 CENT CIGAR

is a 5½ inch, long, slender, hand-made smoke with all our reputation back of it

It has the choicest selection of aromatic, long clear Havana filler

It is wrapped in thin, neutral Sumatra.

It is made by clean, adult hand labor under the eyes of visitors

And first, last and always, it's famed for **mildness—mildness** without sacrifice of the exquisite Havana aroma.

HERE'S THE POINT!

If you're not "hitting it off right" with your cigar, it may be because Cuban-made cigars are too oily and heavy for your nerves

Strike a sort of compromise—without any sacrifice Give up Havana-wrapped cigars for Havana-filled **Wabon Panetelas** made by the pioneer quality cigar house of **Waitt & Bond.** Smoke a cigar that will soothe instead of jangle your nerves.

Send us $2 00 and we will send you a handsome cedar package of **25 Wabon Panetelas.** Smoke five, if you don't like them return the balance, and your $2.00 will go back to you by next mail

WAITT & BOND, Inc., 718 Columbus Ave., Boston

MODERN ELECTRICS & MECHANICS

"The Magazine That Is Different"

You should take at least one non-technical magazine and keep up-to-date on the new wonders and advances in electricity and mechanics. Modern Electrics and Mechanics illustrates and describes these subjects in a style that you will easily understand and enjoy. It contains from 128 to 160 pages monthly and is full of instructive and valuable articles on how to make things at home, and answers your questions free. 15c per copy on news stands, $1.50 per year by subscription

To acquaint new readers with this distinctive magazine we will send a three months' trial subscription for 25c, stamps or coin.

Can you think of a better investment for a quarter? Better send today

Good Lubrication

(Concluded from page 74.)

not only necessary that the compression should be secured, but that it should be secured by proper means.

The troubles attendant upon poor compression in the cylinder are well known to most motorists. Under these conditions a motor is frequently unable to take a hill at all, and in any case the speeds must be changed in order to accomplish it. This is the case even where the same motor with good compression will not have the slightest difficulty in negotiating the same grade at top speed.

Good Adhesion Necessary in an Oil.

It is, therefore, evident that in order to maintain the good compression in the cylinder and at the same time avoid excessive wear and tear, due to metal to metal contact, it is necessary to have an oil which will adhere to the cylinder walls, filling the space between the piston rings and cylinder walls so that compression is secured and the metal surfaces are still kept apart. If the lubricating oil used is too light or is not of such a character as will provide this, the piston rings and the walls of the cylinder will come together so that there is excessive wear, resulting in a larger clearance at some points in the cylinder, in a difficulty in securing as much compression as ought to be secured, and in a much more rapid replacement of parts in order to maintain a working condition at all

It is, of course, possible to run a motor for a certain length of time on any kind of lubricating oil, and it may be months before the difference in lubricating oil will begin to show itself. Unfortunately, however, when the difficulty becomes obvious the damage is practically all done.

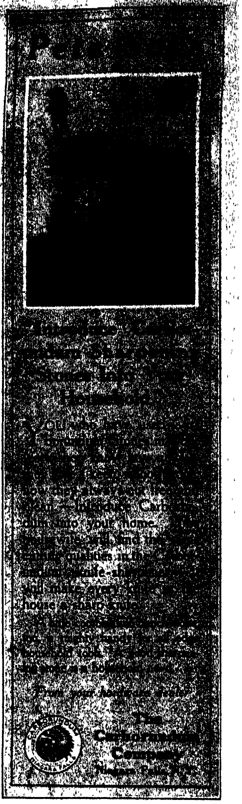
In this connection it may be stated that, while the different motors have different systems of lubrication to some extent, and while these different systems may require slightly different grades of oil, this is not true of all oils or of all the modifications of the systems. Practically all systems of lubrication in use can be divided into three general classes and combinations of these classes. They are—splash, force feed, and circulation systems—and the difference in the oil required for these different conditions of lubricating systems is merely a difference in body, due to the mechanical limitations and not a difference in character. It is true that some of the oils on the market are so manufactured as to be suitable only for a limited number of conditions, and in such cases variations in motor and lubricating system design may require modifications in the character of the lubricant.

It is probable, however, that there are more grades of lubricating oil in use than the mechanical conditions would warrant, and the right character of oil is much more important than a specific grade.

Changing the Oil in the Crank Case.

For all systems of lubrication, and particularly with the splash system and the modifications thereof, it is very important to see that the lubricating oil in the crank case is changed a sufficient number of times, particularly if there is any leakage of the air mixture into the crank case during the compression stroke. It frequently happens that there is a slight leakage on each compression stroke sufficient to allow a certain amount of gasoline to get into the crank case, where it condenses in the lubricating oil, making the oil absolutely unfit for further use, and increasing the cylinder wear-and-tear out of all reason. Motors have frequently been run for 200 or 300 miles with lubricating oil in the crank case which was absolutely useless, as far as preventing wear-and-tear was concerned, and which performed its only service in carrying away some of the frictional heat so that there was no freezing of the engine.

In one case which came to the writer's notice, after the car had been standing for some time, a repair man opened the crank case, lighting a match in order to examine something inside the case, was surprised at an explosion sufficient to seriously burn his hands and face. This explosion was undoubtedly due to the presence of gaso-



dum into your home.

12,000 Electric Trucks

are operating in the United States today

THE NUMBER IN CHICAGO HAS INCREASED 400 PER CENT IN THE LAST TWO YEARS

IN EVERY INDUSTRY there is an opportunity for more efficient methods of transportation and delivery. You can accept this opportunity by adopting the Electric Truck. Used in 76 different kinds of business in New York City alone—so that its ***economy, durability and reliability*** may easily be investigated and proved.

Edison Storage Batteries

Have Made the Electric Truck Practicable

Scarcely five years ago the "Edison Standard" was created by the advent of the Nickel-Iron, Alkaline Cell. Such improvements as have been claimed for competing storage batteries since that time may be traced ***directly*** to the "Edison Standard" and attempts to approach the exclusive advantages of the Edison Alkaline Storage Battery—such as light weight, freedom from inherent chemical defects and practically indestructible construction.

There is no other Storage Battery as light as the Edison. It is the only one that is free from sulphation and sedimentation—the only one that can be left idle without partially or entirely destroying itself by internal deterioration—the only one that may be short-circuited without injury.

The Edison will stand *ten times* as much flagrant electrical mistreatment or mechanical abuse, as any other. Its capacity is guaranteed for four years but experience shows that it will outlive its guarantee many times over

Strong statements, but proved over and over again by competitive tests and by the testimony of the users of over ***one-third of the Electric Trucks.*** Will you be guided by the judgment of leading and largest users and most careful purchasers?

EDISON STORAGE BATTERY COMPANY, 132 Lakeside Avenue, Orange, New Jersey

What Does It Cost To Run YOUR Car?

Why does your neighbor run his car at less cost than you do yours? *Not* that he is a better *driver* than you—or more careful—but simply that *he knows cars better than you.*

Every time you pay a bill—and particularly at the end of the year when you foot up the total cost—you ask yourself this tremendously important question: "How can I run *my* car at less cost?"

The answer is presented every week—for *your* benefit—within the pages of

THE AUTOMOBILE

This pioneer weekly publication is the recognized authority of the industry and gives technical information about cars written so that the layman can easily understand. Your car—your neighbor's car—is taken apart, dissected, analyzed.

THE AUTOMOBILE features the subject of the proper use and maintenance of *your* automobile — how to reduce cost — how to get *more* pleasure and profit out of it. Tells about the latest assessories and accurately interprets the trend of automobile designing, so that you will know what to look for in the next car you buy. One mistake avoided in buying a new car may mean hundreds of dollars saved.

Last week there were articles in THE AUTOMOBILE that you should have read—others are being told this week—additional ones *will* be told next week. *Don't miss any more of them.*

Send $1 for a Special Trial Subscription

For a one dollar bill you'll get THE AUTOMOBILE for 4 months—18 interesting numbers, including the BIG FIVE show issues.

These show numbers (25 cents a copy) are in themselves worth more than the price. They'll contain a comprehensive account of the national automobile shows. Even better than being at the shows is to study the exhibits as they are presented upon the pages of THE AUTOMOBILE.

Tear out this page: Pin a dollar bill to it. Write your name and address in the margin. Send it to us today. Your subscription will start with the current issue.

The Class Journal Company

239 West 39th Street New York City

line in the lubricating oil in sufficient quantity and its evaporation into the surrounding atmosphere.

It is evident from a careful study of motor lubrication that the character of the lubricating oil and system not only have a direct bearing upon the wear and tear, but also upon the power developed and the consumption of the lubricating oil, and of these it is probable that the difference in power developed is alone sufficient to more than pay for any difference there may be in oil cost. It is, of course, obviously impossible for any man in the ordinary running of his car to test as thoroughly as advisable the effect of a lubricating oil. It is true that the effect of the oil in practical work on the road is the important effect, and if the motorist is given to careful and accurate recording, he can by cleaning his machine thoroughly, by putting in an exact quantity of oil, by running over a specified course, using a certain speed or gear change on the hills, seeing that the atmospheric conditions are as nearly as possible alike, and using the same gasoline in both cases, determine the effect of his lubricating oil closely and accurately. If he keeps his accounts fairly well and understands how much it costs for repairs and replacement to his car, he can determine without such testing whether there is any difference in the use of one oil over another, particularly in the replacements of spark plugs, regrinding of valves, and in the cleaning of cylinders, but in this case he obviously must cover a great deal longer time, and his decision will be correspondingly delayed.

As a matter of fact, the only feasible way for the motor owner to do in determining the value of different oils, is to confine his buying in the first place to one or other of the several well-known brands of oil which have, what the lawyer would term, *prima facia* evidence of their value and then by keeping an accurate account of the power developed, of the consumption of oil, of the deterioration of oil in his crank case, of the carbon deposited on valves and spark plugs, determine the *oil which is best suited* (from the results it gives) to his machine and after such careful determination stick to the material which has shown itself to be the most adaptable and the best.

The Importance of a Clean Lubricating System.

The oil, however, is not to blame for all the misfortunes that happen to his motor, nor is the owner absolved from his duties when he has bought an oil which he has every reason to believe is good for his machine. Some care is required in attending to the lubricating system so that the proper amount of oil, without dirt, is fed to the moving parts. In the splash system or in modifications of it, where the oil is carried from the crank case and returned without filtering, it is important that the crank case should be cleaned frequently, as the constant dipping of the connecting rods into the oil will keep any particles of grit, suspended through the liquid so that they are carried into the moving parts of the motor with a very speedy damage to such parts.

Furthermore, if the oil in passing through the system and back to the crank case tank is filtered, the filtering material should be removed and replaced frequently enough to insure its working at all times. The pipes which carry the oil to the various parts of the machine should be examined from time to time to see that they are clear and clean, and particularly in the winter time (unless the oil is of such a character that it will withstand practically any ordinary temperature without congealing), care should be taken that the pipes do not become clogged with congealed oil when the motor is standing.

The question of lubricant, or the transmissions and differentials, the magneto, etc., as well as grease for the axle bearings, etc., is of just as much importance as the lubrication for the motor itself. The difficulty of determining the effect of such lubricant is in this case, however, increased so that it is practically impossible for the motorist to determine as between a number of fairly good lubricants which are the best and most advantageous, and there is only one safe rule in this case, and that is, to buy the lubricant from the manufacturers who are supplying the motor owner with the most suitable cylinder lubricating oil.

Nothing gives less indication of its practical efficiency as lubricating oil. Color is not indicative, as two oils can be practically the same color and produce entirely different results from the standpoint of saving wear and tear, replacement and repair cost. Even the character of the crude has little bearing upon the value of the oil itself, and the only oil which is worth the motor owner's attention is the oil which proves in your machine that it will keep down the replacement of sparks plugs, regrinding of valves, cleaning of the cylinders, keep up the power, eliminate as far as possible deterioration in the crank case due to leakage from the cylinders. These are indications of its value which cannot be mistaken and which do not depend upon hypothetical determinations or tests the value of which the motor owner has no means of judging.

Adaptability of the Motor Truck

(Concluded from page 12.)

While the first of these, translated into its motor truck equivalent, is important, the second is absolutely vital, because here is where the big loss in operation most frequently takes place. Working a motor truck to its true capacity is a dark mystery yet to the average owner—and chiefly because he lacks the data on which to base his system.

Accurate recording instruments, giving mileage and periods of travel and idleness, are as vital to the truck as gasoline and oil if it is to be properly used.

The remaining principles, when they are applied to the truck, become a part of the second, in that they contribute to securing the maximum of productive activity.

The manufacturer must get materials promptly to the lathe and remove its product quickly. So must the motor truck be loaded and unloaded in the shortest possible time. And it will pay in the long run to remodel shipping rooms and loading platforms, install conveyors or interchangeable or dumping bodies as required, or, if necessary, to increase the loading crews. Idle time at several dollars an hour will quickly eat up the worth of the improvements. It is paying executives to tour the country with their architects, to study loading conditions and to build to keep pace with the revolution caused by new transportation methods.

As in the case of all other productive machinery, the operator must be skillful. Bonus systems, schooling, accurate impersonal and impartial supervisions, and high wages to good men will pay dividends in the delivery department. An expert repair man, or, failing that, a driver who has an incentive to show an efficiency record and the means of showing his efficiency conclusively by reason of the accuracy of the owner's knowledge of the truck's work, can save his salary many times over by a daily inspection and tuning up. Reckless maintenance promises of the salesmen have made the buyer indifferent to his own responsibilities. The lathe is not expected to be abused and repaired by the maker; neither should the motor truck.

To establish such ideals of efficiency as these calls for co-operation, education, and a revision of standards on the part of everyone connected with the problem. When the size of the industry is considered, it is clear that the successful solution will affect the well-being of the entire community by lessening the increasing cost of the distribution of commodities.

Wright Automatic Stabilizer for Aeroplanes

(Concluded from page 17.)

izing plane, but a series of small ones, strung out over the whole lateral extent of the aeroplane. It is a defect of design in the device shown that the moving parts are too self-supporting, so that they are heavy and inert, whereas they could every-

IT'S A WHOLE LOT MORE IMPORTANT

That You Have Good *Bearings* in Your Car Than That You Have a Good Self-Starter, or *ANY* Self-Starter

The better-car manufacturers are to it FIRST that you get good BEARINGS. Then they ALSO see to it that you get a good self-starter and OTHER good and up-to-date equipment.

But—a few car manufacturers give you the sort of bearings that cost them the least money, and attempt to sell you their car on the strength of some good self-starter, because they have an idea that this good self-starter is going to make you think that the CAR ITSELF must therefore be good.

The self-starter isn't going to keep your car out of the REPAIR-SHOP, nor is the lighting system, nor is the speedometer, nor is the top, nor is the twelve-inch upholstering nor any of the other necessary, but decidedly MINOR features which they attempt to blind you with.

If you want your car ON THE ROAD, if you want it to cost you little to RUN, go deeper than the mere starting of it. Go right down to the vitals—the BEARINGS—the little parts that take the WEAR and therefore determine the LIFE of the car.

The manufacturers of the better cars in the low-price field, as well as those in the medium and high-price fields, give you bearings and bushings of—

NON-GRAN

And They TELL You So

Manufacturers who skimp on these little bearing parts (which are way inside the mechanism of the car and which you can't see) say NOTHING about their bearings, and draw your attention right up to the self-starter and the beautiful lamps.

To REPLACE a worn bearing (and a worn bearing MUST be replaced) will cost you anywhere from $25 to $200, depending upon how much labor is necessary in tearing down to REACH the bearing.

It's better to pin your man down BEFORE you buy, and judge a car by its VITALS rather than by its ACCESSORIES—important as these accessories may be.

EVANSTON, ILL., U.S.A.

where be supported on stationary parts, and then be broken up into a multiplicity of small units of far less total inertia and proportionally greater strength. Restrained by the "stops" at 9, the plane 5 must be made almost impractically heavy, so as not to be warped out of shape or broken by the wind. A great number of smaller planes would also make the average air pressure on the stabilizer almost identical with that on the main aeroplanes and do away with the difficulty previously pointed out. The many small "parallel motion" frames would then have to pivot on a common shaft.

It remains still to be pointed out that the front elevator shown is less suited to automatic control than the rear horizontal rudder which will doubtless be actually used. If the front rudder is swung suddenly, it may easily get the machine into a situation where its reversal produces no further effect. It will quickly turn it around its transverse axis, with the weight concentrated along that line, but the relative wind will not change accordingly. The machine will "coast," first moving on in the old direction because of its momentum. This will increase the effect of a front elevator; the machine will "buck" so violently, that the reversed rudder will become merely parallel to the relative wind, and a tail slide will be inevitable.

If there is a minimum of "internal work of the wind," the device shown may work well and, safeguarded by the hand control 10, prove a labor-saving device like the pendulum. By an ingenious arrangement the parallel motion may be so adjusted during flight by pushing out or pulling in the handle 11 (held in place by friction) that the plane 5 will then keep the main planes at an ascending or descending angle of attack and thus stabilize a long *vol plané* or a climb just as well as horizontal flight.

During a recent visit of Mr. Orville Wright to New York, it developed that the actual stabilizer used exhibits essential differences from the patented device, although it may be said to work by the same principle. It was revealed that electrical contacts play a part in transmitting impulses which would be greatly in favor of a graded effect, that an entirely novel correcting device counteracts inherent deficiencies of pendulum control, and that the horizontal rudder is indeed in the rear; also, especially, that the weights are now in every direction concentrated as much as feasible at one point, to guard against inertia and momentum effects. Thus modified the apparatus is stated to have worked successfully in long daily flights even in winds of from twenty to twenty-five miles an hour. Changes merely in the angle of the relative wind may apparently be coped with by stabilizers of the Moreau or the perfected Wright type. The fact that the automatic mechanism has proved serviceable in winds of twenty to twenty-five miles an hour, is not astonishing if the wind was uniform or if such variations as were manifest were confined to a change in direction only. The difficulties to be most feared are those which accompany violent changes in the strength of the wind. It also was found necessary to cut out the automatic control in landing.

Mr. Wright is certainly better equipped in every way to develop such a difficult mechanism than most others, and if it should work half as well under critical conditions, as it is said to under normal conditions, its publication on the tenth anniversary may prove to be fully as important as the first announcement of the aeroplane itself. It was stated that barely a touch of a lever for steering was all that was needed.

A Record Balloon Voyage

A DISPATCH from Perm, on the border between European and Asiatic Russia, announced the arrival on December 21st of a German balloon which made the flight of 1,740 miles from Bitterfeld, Prussian Saxony, without a stop in eighty-seven hours. This beats the record of the French aeronaut, Bienaime, who made a

Every Road a Boulevard

To the Car Equipped With Detroit Springs

—In the comfort and safety enjoyed by passengers, and in the freedom from racking strain on car mechanism.
Because Detroit Springs are flexible to a degree never approached in other springs—not only resilient—but softly and gently ***flexible,*** distributing any jar over a long, slow dip and rise.

Detroit Springs Are Silent and Self-Lubricating

The only automobile springs that possess this feature. Near the end of each leaf is an oil cup that feeds constantly between the leaves, causing them to slip silently and smoothly one over the other with never a sound and with a smoothness of action that adds greatly to the riding comfort of the car.

Specify Detroit Springs

You are not only ordering springs with the self-lubricating feature, but inherent quality that can not be seen—springs that have been tested for quality, hardness, resiliency and capacity
You are insuring your own comfort and safety as well as the life of your car.

Completely Guaranteed For Two Years

The date of manufacture is stamped plainly on each spring and for two years from that date we will replace without cost any Detroit Spring that "settles," breaks or shows any lack of efficiency due to defective material or workmanship This printed guarantee is issued by the car manufacturer or by us direct if desired.

QUESTIONS AND ANSWERS ON AUTOMOBILE DESIGN, CONSTRUCTION AND REPAIR. By Victor M. Pagé, M.E. New York: Munn & Co., Inc. 5¼ by 7½ inches; 622 pp.; 329 illustrations; cloth. Price, $1.50 postpaid.

We can name no writer better qualified to prepare a book of instructions on automobiles than Mr. Victor W Pagé His experience for years as technical editor of a motor-car journal taught him what the public wished to know, while his training as instructor in automobile schools showed him how to impart this information to others in simple language. His previous works, "The Modern Gasoline Automobile" and the "Trouble Chart," by which the location of gasoline engine troubles was made easy, are widely known among automobilists Soon after their publication many letters were received asking the author to prepare a more elementary work which could be sold at a lower price The present work is an answer to these petitions It is written in the form of a catechism, beginning with the very rudiments of automobile engineering, and presupposing no previous technical knowledge on the subject Not only pleasure vehicles but commercial vehicles, as well, are included in the work Special care is taken with the logical arrangement of the various topics There are about two thousand questions and answers which take up in a practical way every detail of the machine with which the owner is liable to be concerned It is written for that vast army of motorists who cannot afford to hire a chauffeur and must take care of their own machines It is written, as well, for the man who can afford to pay for the care of his motor car but is not willing to be imposed upon by a dishonest chauffeur working in collusion with unscrupulous repair-men The book is copiously illustrated with drawings and photographs, showing the latest domestic and foreign practice.

AMERICAN TELEGRAPH PRACTICE. A Complete Technical Course in Modern Telegraphy, including Simultaneous Telegraphy and Telephony By Donald McNicol, A M, A I.E E. New York. McGraw-Hill Book Company, 1913 8vo, 507 pp, illustrated Price, $4 net.

American systems are handling a hundred telegrams to-day where ten years ago they could take care of but fifty and the time of transmission between distant points has been cut in half The work in hand conveys a clear idea of the way in which this development has been brought about Existing systems and modern methods of operation are described and the mathematical formulæ are so worked out as to be readily mastered by all who understand arithmetic and elementary algebra

THE NATURAL HISTORY OF THE TORONTO REGION Ontario, Canada Edited by J H Faull, B A., Ph.D, Associate Professor of Botany, University of Toronto Toronto. The Canadian Institute, 1913. 8vo.; 419 pp; with maps and illustrations. Price, $2.

The articles comprising this work are the authoritative utterences of specialists, and well worth the study of any who may have an interest in the natural history of the city and its vicinity History geology, and climate are touched upon, and the flora and fauna are described in a series of papers that present their respective subjects in a well-arranged and accurate manner The work is rich in maps no less than three being carried in a back pocket of the book while others appear as folding inserts or full-page charts These graphically present such subjects as the life zones of eastern North America a road map of Toronto and environs and maps of neighboring countries

THE HEART OF GASPÉ Sketches in the Gulf of St Lawrence By John Mason Clarke New York The Macmillan Company, 1913 8vo, 292 pp.; illustrated Price, $2 net

Gaspé, whether regarded as a county or a peninsula is the northeastern outpost of Quebec It is larger than Massachusetts, its wild coasts sparingly dotted with villages, whose settings, modes and customs are survivals of remote ages The author characterizes the inhabitants as invariably kind and hospitable, wresting their scanty livings from reluctant soil and sea His pen-pictures of their rough yet fascinating country are enhanced by glimpses of history and information regarding its place names Many illustrations of natural scenery, native architecture, and seabirds and their haunts enliven the pages of a narrative that without any attempt at fine writing, yet conveys with a simple fidelity the rugged charms of a territory whose features will be new to many readers

ON HEROES, HERO-WORSHIP, AND THE HEROIC IN HISTORY. By Thomas Carlyle. Edited, with Introduction, Notes, and Bibliography, by Herbert S. Murch, Ph.D., Instructor in English in Princeton University. New York: D. C. Heath & Co., 1913. 12mo.; 313 pp.

This new edition of Carlyle's inspiring and illuminating work has been prepared by Prof Murch with particular care toward the needs and limitations of those just entering upon the study of Carlyle The biographical introduction is immediately followed by a discussion of the style, plan and teachings of the work, in which certain difficulties are explained away, and the student is enabled to approach the lectures in an understanding manner. The profuse notes are a further aid toward clarifying the text to the beginner's mind, and a bibliography for supplementary reading will prove to be an appreciated feature

The Interlaken School

Prepares boys *for* work *by* work. A unique school community that lives in the open, governs itself, and builds and operates its own equipment, Instruction includes careful teaching of the old essentials and gives thorough preparation for college or university. Graduates of Interlaken may spend a year in affiliated schools in Europe. Next session begins January 5th; summer camp opens June 15th; camping expeditions on shores of Lake Michigan—horseback excursions cross-country will be provided during summer. For further information address Edw. A Rumely, Pres. The Interlaken School LaPorte, Indiana

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12888) C. S. is informed that no inquiries are answered unless the full name and address is given. We do not make any broad statements as to who make "best" revolvers, etc. The concern you mention by name makes a reliable article.

(12889) C. U. asks: Kindly tell me what is the scientific reason for the effect which oil has when poured on tempestuous waves. A The spreading of oil over the surface of water is due to the fact that the surface tension of the oil is less than that of water. The water draws the oil over its surface by reason of its greater surface tension The oil on the other hand has a very great viscosity, and the film of oil on the water holds the surface of the water from breaking into ripples. The waves therefore become smooth, and although they are still very high, they roll smoothly by and do not break over the vessel. The vessel rises easily and rides over the waves, which without the oil broke over the vessel.

(12890) J. W. McC. asks: I am anxious to get in touch with some schools that have divided or rather segregated the boys and girls in the physics work. We are doing the work on this line this year, but have not been able to find a suitable text for the girls. This is what I am after Any information will be appreciated. A We do not know any schools in which the *girls* are taught physics in classes separated from the boys. Physics is usually taught as a branch of mathematics in high schools and most colleges, and the subject is divested of most of its interest for young people for this reason. A text book based upon the experiment and not upon the formula is much to be desired. One appeared this year which is very attractively gotten up, by Millikan and Gale, which we send for $1 40 postpaid It is called "A First Course in Physics," and is almost wholly descriptive. No similar college text book has appeared.

(12891) J. W. B. asks: As I have not missed a number of the SCIENTIFIC AMERICAN in forty years, I now for the first time ask a favor. I want to know what material is the best insulator to fill a 1¼-inch space between the inner and outer side of an ice box. Sawdus is not much good, and air space cannot be perfectly confined. A Charcoal has been used more than anything else in filling the walls of refrigerators, though wool should be just as good Anything which will prevent currents of air will answer the purpose, one thing is about as good as another. Sawdust will do this, and it is not a conductor of heat There is nothing which will act absolutely to prevent the passage of heat. A vacuum is the very best insulator against the passage of heat, but this is not practicable in an ordinary refrigerator

(12892) D. L P. asks: Please tell me how to make an amalgam with silver and mercury A In the preparation of silver amalgam, pure silver must be used If the silver is in the powdered form, the amalgamation is more easily brought about The silver powder can be prepared from a solution of nitrate of silver, one part in 10 to 15 parts of water Put this solution into a bottle and shake it with a few small pieces of sheet zinc The silver will be precipitated in a few minutes. When the powder has been washed and dried it is ready for use The silver can be dissolved directly in the mercury, but a quicker method is to heat the mercury nearly to its boiling point in a crucible, and add the powdered silver, stirring meanwhile vigorously with an iron rod Silver amalgam can be prepared in the cold by making a solution of nitrate of silver, 1 part of nitrate by weight to 3 parts of distilled water and adding 4 parts of mercury to this solution. The combination will take place by shaking the mixture This process is taken from the "Scientific American Cyclopedia of Formulas," price $5, which contains nine pages upon the formation and uses of amalgams.

(12893) L. G. B. asks: I find plenty of information in the Encyclopædia Britannica and elsewhere on the dynamics of real gases with elastic molecules How would the inelastic and frictionless particles of a hypothetical gas consisting of such particles behave? What directions would they take after collisions? Please refer me to literature discussing this. A. A frictionless, inelastic particle could not take any direction after collision with another similar particle. It could not rebound at all. It would lose all its momentum on collision and there would be no restitution for a rebound, since it is inelastic. We have no references to any literature of this subject Balls of lead are sufficiently inelastic to illustrate this. They do not rebound from each other after collision, as in the familiar experiment in physics

(12894) C. A. H. asks: A small tube closed at one end and filled with water will retain the water when held perpendicular with the open end down. This is due to atmospheric pressure. A claims that the same thing would happen in a pipe or tube of any larger dimension if the tube was held absolutely still. B claims that the water would fall if the diameter of the tube were larger. Which is correct—A or B? If B is correct, would like to know how large the diameter of the tube would have to be before atmospheric pressure would cease to retain the water therein. A. The tube closed at one end, filled with water and inverted, will retain the water if the diameter of the tube is small enough to be called capillary If larger than this, the water will run out The surface tension of water has a large part in the support of the water in the tube We cannot give the diameter of the largest tube which will support water in this manner, but we have seen it done with tubes as large as a tenth of an inch.

(12895) O. O F asks: Please insert an answer to the following questions in the Notes and Queries section of the SCIENTIFIC AMERICAN 1 What is the difference in feet between low tide and high tide on the ocean or on the Atlantic coast generally? A On the open ocean the difference of level between high and low water of the tides is 2 or 3 feet On the Atlantic coast it varies *from 2 to 3 feet up to 50 to 60 feet* 2. How far into Delaware Bay, Chesapeake Bay, and Long Island Sound does the tide reach with the same difference between low and high tide as on the ocean? What is the depth of these inlets at the mouth? Where can I buy a book containing similar information of any part of the world? A We have not this information, and do not know where it can be obtained in any single book The various books of sailing directions which navigators have for their voyages will give it for the different ports which they cover The United States charts of the coast will give the depth of water at all parts of the coast These books and charts can be purchased from dealers in nautical instruments. We would add that a high tide flows into Long Island Sound through New York Bay, and meets a low tide which enters the Sound from the east near Hell Gate, thus making the rough water and dangerous currents of that narrow passage and causing less rise and fall than if a single tide was in the Sound. Six hours later the tides are reversed, with the same result The same action takes place in many parts of the world around a large island. 3 Does a propeller, similar to those used on aeroplanes, with a given power, have as much pulling force as a vehicle with the same power applied to the wheels? If not, how much less? If air were forced out from the rear of a vehicle with great force, would the propelling force equal that of a propeller with the same power? *If the air were drawn in from the front,* with great rapidity, leaving a partial vacuum, would the propelling force equal that of a propeller? A A propeller working against a very mobile fluid like air does not have the same propelling force on a vehicle as when the same power is applied to the solid earth by the wheels Jet propulsion has been tried in water with no valuable results excepting the gaining of experience and, as Mr Edison once said about some unsuccessful experiments "learning what cannot be done" It does not seem to be possible to get the same power from a jet as from a propeller A vessel was built in recent years for jet propulsion with no success

(12896) W S E asks: Please tell me through your columns why you can cut glass under water with a scissors A We have not been able to cut glass under water with shears in such a way that both pieces can be used We can chip off the edges of a piece of glass under water The pieces cannot fly in the water as they do when one cuts them in the air, but the crack often extends in a direction different from the one in which you wish it to go and the piece is spoiled We should say that glass cannot be cut with any precision under water with a pair of shears The water seems to assist the shears in biting on the edge of the piece of glass, and to hold the pieces from flying about

(12897) E. P V. asks A asserts that the earth moves faster at the equator than at any other place B asserts that as the earth rotates as a whole, no one portion of it can move more swiftly than any other portion A asserts that the angular velocity is the same but that the linear velocity is greater at the equator than at any other point As you are doubtless familiar with the general trend of such discussions, the pros and cons of this particular one will not be repeated Which is right? A. The earth rotates with the same angular velocity in all latitudes. The relative linear velocity is therefore the same as the lengths of the degrees of longitude The degree of longitude at the equator is 69 16 statute miles in length. At your place it is 58 05 miles, in New York it is about 52.25 miles, and at the pole the degree has no length. So while the earth's surface moves 69 miles at the equator, it moves 58 miles at your place and 52 miles at New York. If you will take an orange or a lemon and turn it in your hand as the earth turns on its axis, you will doubtless see why this is the result in the earth.

(12898) W. H. S. asks: I shall be obliged to you if you will please give me the fusing temperatures (melting points) of the following metals: Platinum, iridium, gold, silver, copper, zinc, tin, lead, iron. A. We give you the melting points of the metals which you name in your inquiry, as given in the Bulletin of the Bureau of Standards No. 35, published by the United States Government, Washington, D. C. Platinum, 3,191 deg. Fahr.; iridium, 4,170 deg. Fahr.; gold, 1,945 5 deg. Fahr.; silver, 1,761 deg. Fahr; copper, 1,981.5 deg. Fahr.; zinc, 786.9 deg. Fahr., tin, 449.4 deg. Fahr.; lead, 621.1 deg. Fahr.; iron, 2,768 deg. Fahr.

THE MODERN
GAS TRACTOR

By VICTOR W. PAGE, M. E.

Author of "The Modern Gasoline Automobile," Etc

A COMPLETE TREATISE DESCRIBING ALL TYPES AND SIZES OF GASOLINE, KEROSENE AND OIL TRACTORS. CONSIDERS DESIGN AND CONSTRUCTION EXHAUSTIVELY; GIVES COMPLETE INSTRUCTIONS FOR CARE, OPERATION AND REPAIR; OUTLINES ALL PRACTICAL APPLICATIONS ON THE ROAD AND IN THE FIELD. THE BEST AND LATEST WORK ON FARM TRACTORS AND TRACTOR POWER PLANTS.

5¼x7½ Inches. Cloth. 475 Pages. 204 Illustrations. 3 Folding Plates.

PRICE $2.00, POSTPAID

A modern exposition in the language of the field showing and describing every recent improvement in tractors and auxiliary appliances All money-making farms use power. Learn how to apply it now.

This work is written by a recognized authority on self propelled vehicles and internal combustion motors Everything is explained so simply that anyone of average intelligence may obtain a comprehensive knowledge of *gas tractor operation* maintenance and repair Tells how they are constructed and explains fully the reasons for varying designs Contains special chapters on driving the tractor on field and road, what to expect from tractors in various kinds of work, cost of operation and money making hints on repairs It describes all ignition systems all types of gasoline and kerosene vaporizers and carburetors latest forms of power plants and installation, clutches speed changing and reversing gears and all *frame parts and their functions* Tells how to tell brake horsepower from draw bar or horse equivalent power how to make adjustments to power plants change speed gearing and other parts Describes tools for tractor repair and gives plans for tractor sheds so they can be used in winter for stationary power or workshops where all repairs may be made Outlines control systems of leading types and shows simple hitches for working various implements in combination Describes fully tractors for small farms and orchards as well as types of the largest capacity All illustrations are plainly marked with all important parts indicated so they may be easily identified Drawings are simple but in correct proportion Every illustration has been specially made for this book

ALL FARMERS, STUDENTS, BLACKSMITHS, MECHANICS, SALESMEN, IMPLEMENT DEALERS, DESIGNERS AND ENGINEERS NEED THIS WORK

Written in language understood by all. No technical terms.

COVERS EVERY PHASE OF 1914 TRACTOR ENGINEERING PRACTICE AND IS SUPERIOR TO ANY TREATISE HERETOFORE PUBLISHED

YOURSELF

After all, the most important thing in the world to you is YOURSELF. Your success in life is decided by the kind of person you are.

Your Personal Efficiency

To increase your own Personal Efficiency only ten per cent. may mean thousands of dollars to you —or success worth more than dollars. It may save your job, or your profession, or your business, or your health and happiness

You Can Learn from Emerson

To meet a wide demand for a course of training in Personal Efficiency, a series of twenty-four lessons has been prepared by Harrington Emerson, the noted Efficiency Expert.

These lessons are now offered to the public through the Institute of Efficiency. A splendid organization, enthusiastic support by other efficiency experts, make possible scrupulous individual care at a very low cost.

Fascinating and Profitable Lessons

The great principles of efficiency have been applied to YOURSELF by Mr. Emerson. In these fascinating lessons you are shown how to make the most of your own abilities and circumstances.

Mr. Emerson has been in efficiency work for many years; he has also been a teacher of men. He has put into these lessons his experience. You are told how efficiency principles, if applied, will add to your ability to *make money*, to *save money*, to *do work*, to *plan time*, to *maintain health*, to *acquire knowledge*, to *master your job*, no matter what it may be. This applies to you—ask us and we will tell you how.

HERE IS A MANUFACTURED CAR And IT IS MANUFACTURED RIGHT

The Winton Six is a **manufactured** car, not a mere assemblage of gathered parts. If you do not fully realize the tremendous difference between manufactured and assembled cars, let us tell you—or, ask any other bona-fide car manufacturer.

One Model Exclusively

This is the car that put sixes on the map. The present model is now in its seventh consecutive year of success, and is free from experimental risks. Our great factory produces this **one** model exclusively. We do not make trucks. The Winton Six is made by the world's pioneer and most experienced six-cylinder specialist, Alexander Winton.

Power and Stability

The Winton Six has all the power a fine car needs. Society of Automobile Engineers' rating, 48 H. P. We make no exaggerated claims of horse-power. The car is stout and enduring. Light cars rack themselves to pieces, but the Winton Six is substantial, safe, and dependable. A car you can trust anywhere at any time. Most economical of cars; holds the world's lowest repair expense record, based on millions of miles traveled by individually owned Winton Six cars. Ask for the full figures.

Comfort and Service

Original self-cranking car. Seven years of success for the Winton starter. Luxuriously comfortable. Most restful riding car on American roads. Try it and know for yourself.

WINTON SIX

Long stroke motor, left drive, center control, electric lights, self-starter, finest mohair top, easily handled curtains, rain-vision glass front, best Warner speedometer, Waltham eight-day clock, Klaxon electric horn, rear tire carriers, four cylinder tire pump, demountable rims, full set of tools, German silver radiator, metal parts nickel finished. Fully equipped, $3250

Every Winton Six buyer gets from us a Service that is cheerful, genuine, and thorough—the delight of car owners.

Fully equipped with the best of everything. Price of the Winton Six five-passenger touring car, $3250, and worth the money.

A Safe Purchase

Behind this safe and satisfying car is a Company of rich experience, ample facilities and genuine financial stability. We take the cash discount on all our purchases. We have no outstanding bonds, mortgages, debenture notes. There is no water in our stock, and we avoid overproduction. Quality of output, not quantity, is our policy. When you buy a Winton Six, your investment will not be "orphaned" over night.

May we send you our latest catalog? It gives important inside information about conditions that exist right now in the motor car industry.

The Winton Motor Car Co., 1080 Berea Road, Cleveland, O.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

As to Alaska

IT is nearly half a century since we purchased Alaska. In the interim we have paid so little attention to this vast territory, the largest body of unused and neglected land in the United States—that it is inhabited by less than 40,000 white inhabitants—a gain of less than one thousand for each year since it passed beneath our flag. In the intervening forty-six years we have got from Alaska more than we have given; for it has repaid our inexcusable neglect by adding to our wealth through the yield of its mines, fisheries, and furs alone, more than $500,000,000.

To those who are interested in Alaska—and that should mean every citizen of this country—we commend the report of the Secretary of the Interior for the fiscal year ending June 30th, 1913, an illuminating document, well calculated to awaken a widespread national interest in this neglected country, and a sense of our national duty to provide for its intelligent and systematic development and government. The prospector has proved that no other section of our land makes so rich a mineral promise, and the Government has demonstrated that in agriculture, Alaska will produce in abundance everything that can be raised in the Scandinavian countries. It is estimated that there are in Alaska fifty million acres of land that will make homes for a people as sturdy as those of New England.

The Government has made a start by withdrawing Alaska from the too aggressive and self-serving exploiter, but, as yet, we have done nothing to substitute a safer servant of the public interests. If we are to bring Alaska into the early and full realization of her possibilities, we must create a new piece of governmental machinery for the purpose. Secretary Lane would establish a Board of Directors, and into its hands he would give all the national assets of that territory, to be used primarily for its improvement—its land, fisheries, Indians, Eskimos, seals, forests, mines, waterways, railroads, all in fact, that the nation owns, cares for, controls or regulates. This board would have nothing to do with the internal affairs of the territory, and it would exercise no powers save such as Congress might grant over the property of the United States in Alaska.

The arguments set forth by the Secretary in favor of the above policy are convincing. In the first place, such a board would advise Congress as to what should be done, without prejudice and out of a deep national interest and with first-hand knowledge of conditions. It would co-ordinate the present enterprises of the Government. As matters stand, the control of land is in one department, of forests in another, roads in another, of fisheries in a fourth, and of railroads in still another department. As a concrete instance of these conditions which strikes us as positively funny, we are told that the care of black bears is in one department and of brown bears in another. Every one will agree with the Secretary, surely, that there can be no satisfactory administration of land laws, nor indeed of any other laws, at a distance of 5,000 miles from the point of action. Truly, "the eye that sees the need should be near the voice that gives the order." Alaska's opening and improvement should be treated as one problem, and each step of its administration should be part of a general plan, of a unified and consecutive programme based on immediate knowledge and conditions. The opening of land and the building of railroads or wagon roads, for instance, should be part of one general scheme.

The Secretary believes that Alaska should be developed, so far as possible, out of her own revenues and resources, that she shall have a federal budget of her own, her revenues and expenditures being presented to Congress on a single sheet. The funds raised from her lands and fisheries, her furs, her forests and her mines, should be used for the construction of her roads, railroads, telegraph and telephone lines, or for any other purpose which would make her resources more quickly available to the world. It is believed that Alaska is self supporting to-day. That is to say, that by proper taxes and charges imposed upon those who are deriving large returns from their enterprises in the territory, such revenues could be derived as would support a large policy of expansion and improvement.

Positive and Negative Natural Laws

THERE is something satisfying about a positive statement. To be told, for example, that the gravitational attraction between two portions of matter is equal to a certain known constant multiplied by the product of their masses and divided by the square of the distance between them, is to be given full and sufficient information to determine the gravitational pull between any two portions of matter whose masses and distance apart are given. Here the law is given in the form of an *equation*, which can be solved without ambiguity for any given case.

But not all laws of nature are of this positive type. We are still living in the age of the "heat engine"—our prime movers deriving their power in the great majority of cases from coal, oil or other fuel. Now the performance of which a heat engine is capable is *limited* by a law of physics—a negative law, for it tells us only what a heat engine can *not* do, it does not predicate anything positive about the performance of such an engine. A condensing heat engine dependent upon a source of heat (e. g., a boiler) at 380 deg. Fahr. and performing the coolest part of its cycle at say 100 deg. Fahr., can not possibly have a thermodynamic efficiency greater than 33 per cent. For the second law of thermodynamics tells us that the efficiency of any *real* heat engine, working between two absolute temperatures T_2 and T_1 is less than $(T_2 - T_1) / T_2$. This law, unlike that of gravitation, is expressed by an *inequality*, for which there are necessarily an infinite number of solutions, thus leaving room for ambiguity.

Now it might at first sight appear that such a negative law would be of little practical value. But this is far from being the case, if only because it serves as a warning to us not to divert our inventive energies into fruitless channels. Any attempt to build a heat engine with an efficiency higher than the limit set by the law quoted, represents so much labor wasted—at least so long as we can not deal with individual molecules. This has sometimes been expressed by saying that "perpetual motion of the second kind" is impossible: Thus for example, without any violation of the law of conservation of energy, we might suppose that a vessel traveling on the ocean might derive heat from the practically unlimited source provided for it in the ocean, turn this heat into work for propulsion of the vessel through the water, and at the same time return it to the sea by the friction of the ship's hull against the water. The sea would lose none of its heat, since what was taken from it for the ship's motors would presently be returned to it by friction. Therefore, it would seem, this process might be continued indefinitely. But such "perpetual motion of the second kind" is impossible—the law stated above bars all possible avenues to it.

So far, in fact, from useless are negative laws of nature, that this form is sometimes given to laws which are capable of being stated in the positive form. Thus the first law of thermo-dynamics, the law of conservation of energy, is sometimes stated to the effect that "perpetual motion of the first kind" is impossible—that energy can not be extracted indefinitely from a system which does not undergo some compensating change in the process, but returns at the end of the operation in every respect to its initial state. The value of this negative statement, again, is that it deters the cautious inventor from wasting his efforts in a fruitless quest. We say the *cautious* inventor, who takes the pains to inform himself of the knowledge acquired by others before launching out upon original work. Unfortunately there is never wanting an army of "inventors" lacking this caution, hence the daily growing literature on "perpetual motion" devices.

Limiting Motor Trucks to Preserve the Roads

IN Maryland, and probably in New York and several other States, at this winter's sessions of the legislatures, efforts are to be made to enact measures intended to preserve the public roads and bridges by restricting the weight and speed of motor trucks, traction engines and other vehicles.

Bills of this nature were passed last spring in Massachusetts, New Jersey, and Pennsylvania, and this fall the Commissioners of Highways of New York State issued a set of regulations based on the Massachusetts law. The Bay State and the Empire State regulations limit the gross weight of vehicles with load to fourteen tons, and the weight on any one wheel to 800 pounds per inch of nominal width of tire. They also limit to fifteen miles per hour the speed of vehicles weighing more than four tons with load, and to twelve miles an hour vehicles weighing more than six tons if fitted with rubber tires, or to six miles an hour if fitted with iron or steel tires.

Leading motor-truck manufacturers concede that these limitations are reasonable and are not opposed to them so long as they are enforced equally against all kinds of vehicles and objects moved over the roads. As a matter of fact, there are very few motor trucks in existence that have a rated capacity of more than five tons and which weigh, with full load, more than ten tons. Out of approximately 80,000 commercial vehicles now registered in the United States, less than 400 will weigh as much as fourteen tons with full load, and these are used mostly in large cities where pavements are strong enough to support them. Only a little more than 1,200 out of the 80,000 are of more than five tons rated capacity; for it has not been demonstrated satisfactorily that the larger sizes are economical of operation, at least when fitted with rubber tires. These figures, which are authentic, make it appear that the advocates of weight restrictions are needlessly apprehensive, so far as motor trucks are concerned.

Speed and narrow iron tires on heavily-loaded wagons are more destructive of roads than mere weight, especially when this weight is carried on wide rubber tires. All leading tire manufacturers recommend loads considerably less than 800 pounds to the inch of width for their tires and seek to discourage loading them beyond the specified weights.

The speed limitations of the Massachusetts and New York regulations are not objected to by the motor truck manufacturers, who have striven long and earnestly to discourage overspeeding as well as overloading of trucks. The automobile manufacturers' national association, the Automobile Chamber of Commerce, has adopted standard truck speed ratings that are slightly below the limits fixed by the State regulations, and the standard form of warranty issued with the sale of each truck provides that overspeeding and overloading will void the warranty.

Nevertheless, the manufacturers believe that legislation directed specifically at motor trucks is unnecessary, and that it will have a tendency to postpone the building of permanent roads suited to motor traffic and the rebuilding and strengthening of antiquated bridges of which too many remain. They object to the implication which such legislation carries with it, that the motor vehicle is the only type of vehicle that damages the roads; whereas the highway commissioners and engineers who are advocating these measures never have brought forward any record of scientific observations to show the actual kind and amount of damages done, and they themselves admit that heavy teams are one of the most injurious factors in highway traffic.

Yet owners of automobiles and motor trucks are the only persons who are required to pay a specified tax for the use of the roads; and this is one of the reasons why the motor interests oppose this form of double taxation and discrimination. They are heartily in favor of good roads, but they object to having the funds raised by taxation of motor vehicles applied to building and maintaining types of roads unsuited to motor traffic—particularly when it is through their efforts that large road appropriations have been secured from State legislatures.

Any laws that are passed to regulate motor trucks should be made uniform with those now existing in the largest and most important States. An attempt is now being made by special commissions, appointed by eleven Eastern States, to harmonize the differences that exist between the present motor vehicle laws and to recommend one uniform law for all. Nothing done at this winter's sessions of the legislatures should be allowed to make this task more difficult. It would be better to defer legislation than to create new laws or provisions that might have to undergo radical changes within a year, if the uniform law recommended by the joint commission should be adopted.

Volcanic Eruption in the New Hebrides

THE volcanic island of Ambrym, in the New Hebrides, was recently the scene of one of the most violent eruptions in its history. British and French officials, who visited the scene in the French cruiser "Kersaint," found the western coast of the island, between Dip Point and Banlaw, covered with ashes and scoria, which had fallen continuously for five days, while vast streams of lava had overwhelmed the Presbyterian mission hospital, French and English trading stations, cocoanut groves, etc., but no loss of life was reported among the few European residents. Most of the natives have been transported to another island. Many hundred natives are believed to have perished.

Engineering

Wash Your Smoke.—The New York Edison Company has perfected an apparatus for eliminating the smoke and cinder nuisance at its great Waterside station, New York. The smoke from the boiler plant, laden with soot and cinders, is driven at high speed through a sheet of water, by means of which practically all of the material which constitutes a nuisance is deposited in a big water tank. The recent test showed an average efficiency of extraction of 95 per cent.

Germany's New Gun.—According to the *Army and Navy Journal*, the new gun mounted on the "Ersatz Wörth" and battleship "T" is a Krupp 15-inch piece, presumably 45 calibers in length, which weighs 75 tons and fires a projectile of 1,667 pounds with a charge of 331 pounds of smokeless powder, at an initial velocity of 2,789-foot seconds, and with the resulting enormous muzzle energy of 90,880-foot tons. The possession of such a gun means the ability to hit hard and accurately at very extreme ranges.

A Larger Navy for Defense.—Representative Hobson, in explaining to the House why he considered that the United States was only a third-rate power, referred to the fact that our present small navy, merely in the performance of its police duties, would have to guard 30,000,000 people and 37 billion dollars' worth of property that were concentrated along our seaboard and actually within gunshot of a hostile fleet. He stated that America has more lives and property exposed to such attack than has all the rest of the world combined.

The "Aquitania's" Engines.—The new Cunard liner "Aquitania," which is due in this port early in the coming year, will possess the largest turbine engines ever built. They will weigh 1,400 tons, and they will contain over 1,000,000 blades, varying from 1½ to 20 inches in length. The engines will contain high, intermediate, and low pressure turbines, and will be marked by other improvements suggested by the extensive experience gained by this company with the turbine-driven "Carmania," "Lusitania" and "Mauretania."

Small Navy Yards Should be Abolished.—We are glad to note that the present Secretary of the Navy has stated that it will be his policy to reduce expenditures ashore and use the money so saved for increasing the navy afloat. Rear Admiral Wainwright, who is a strong advocate of building four battleships this year, states that, if the Government would see fit to do away with the small navy yards and increase the capacity of the larger ones, much of the annual expenditure could be used in other directions. In no direction could the money so saved be used to better advantage than increasing the appropriations for new ships.

Lifeboats and Davits.—The International Committee sitting in London has recommended that lifeboats be provided for all on board. If this recommendation be widely accepted, we hope that the future type of lifeboat and davit will be modified to meet modern conditions. Both the lifeboats and the handling gear should be greatly increased in size, accommodation and speed of control. The lifeboat of the type used on the "Titanic" was wofully out of date. Thirty-ton motor-propelled boats, capable of accommodating 250 people, and handled by powerful electrically-operated davits, should constitute the equipment of the large passenger steamer of the present day.

Non-magnetic Rails and Track-signaling.—According to our contemporary *The Engineer*, in order to accommodate the increasing use of track and signaling circuits on railways, with the necessity for bonding joints, points, and crossings, and separating rail sections to form the desired electric circuits, it is proposed by a German engineer to use non-magnetic rails. The non-magnetic track rails are made of nickel steel containing about 18 to 20 per cent of nickel, and they are inserted at desired points in the ordinary magnetic track for controlling signals, brakes, etc., from the vehicles. For light railways, the whole of the track may be formed from these rails, which do not affect the action of the weak electric current used in controlling the railway.

The Transatlantic Record.—The present transatlantic record is four days, ten hours from the coast of Ireland to the entrance to Ambrose Channel, New York. It was made by the "Mauretania." The "Lusitania," on her last westward passage, in spite of strong winds and head seas for the whole voyage, crossed in four days, eighteen hours, five minutes. This performance gives promise of the "Lusitania's" surpassing the record of her sister ship under favorable weather conditions, for during the above-mentioned trip, for a period of eight hours, she made 197 revolutions and averaged 27 knots, and for one hour of this time her revolutions reached 207, the equivalent speed for which would be nearly 28 knots. It is likely that during the coming year the record average speed across the Atlantic of 26.06 knots will be considerably exceeded.

Electricity

Electric Blasting to Prevent Tuberculosis.—The gold mining companies of the Rand field, South Africa, have been experimenting with electric blasting with a view to reducing the danger of miner's phthisis, a disease which is very widespread in that region, and is laid to the fine dust resulting from blasting. By using electric systems the firing can be done from the surface and the air can be cleared of the fine dust before the miners need to enter the mine.

Experiments in Electroculture carried on by the U. S. Bureau of Plant Industry during the past year have not had encouraging results. Electrically treated plats of wheat gave an increased yield of only one half bushel per acre above that of the check plats. In 1912 an increase of two bushels per acre was obtained. None of the experiments conducted by the Bureau has so far indicated that electroculture is practicable from a commercial standpoint.

Electricity Supply in London.—Considerable agitation has been stirred up in London, following the address delivered before the Institution of Electrical Engineers by Prof. G. Klingenberg, Ph.D., on the subject of electricity supply in large cities. He compared conditions in Berlin, Chicago and London, showing that in the first two cities only six power stations are used in each city, whereas in London there are 64, and he showed how much more economical it would be to employ a few large stations. He suggested the substitution of a large power station for 25 of the existing stations.

A Wireless Weather Service on the North and Baltic Seas, under German auspices, has been in operation since the first of last July. The radiotelegraphic stations at Borkum, Heligoland, Norddeich, Cuxhaven, Bülk, Swinemünde and Danzig are regularly supplied by the Deutsche Seewarte, at Hamburg, with telegraphic information enabling them to advise vessels at sea, on request, of the current barometric conditions over Europe and the winds likely to prevail over the North Sea, the Western Baltic or the Eastern Baltic, according to which of these regions is specified in the inquiry.

Magic Wand.—A curious magic wand has been developed in France. It is worked by the action of a concealed magnet, so that a mouse or other small animal appears to run up and down the wand in a mysterious way. The wand is a square tube of light wood covered with silk, and the animal is of celluloid and has a small piece of iron on the bottom. Inside the rod is a small lead weight on an endless cord, and when the wand is turned up, the weight falls gradually and draws along a small magnet, also fixed on the cord and just below the surface. When the rod is inclined, the rat thus climbs up to the top, and this can be repeated as often as one may wish.

Electrically Operated Moving Targets.—Moving targets are used in Germany which are mounted on trucks and drawn along the ground by the use of electrically worked cables and drums, so as to approach real conditions. In the electric plant is a large motor driving a number of drums, one for each cable and its target, the speed varying as desired. Silhouettes representing infantry are drawn along, at first slowly, and when fired at they run at a rapid rate till they reach the first trench, stopping and lowering automatically so as to show only the head. Other maneuvers for infantry or cavalry can be carried out, and the electric method allows of a good control of operations.

Summoning Police by Train Wireless.—The wireless equipment now used on the Lackawanna trains has proved very serviceable on a number of occasions. Recently when an engine broke down, a new engine was summoned by wireless communication and much time was saved. Only the other day the new means of communication was employed to summon two of the road detectives in order to arrest suspected crooks who were found riding between the baggage car and the tender. The detectives were on hand when the train pulled in at Binghamton and placed the men under arrest. No doubt wireless communication between stations and moving trains will prove useful in a thousand and one unexpected situations.

Concrete vs. Wooden Poles.—An electric service company in Abilene, Kansas, is manufacturing its own poles of reinforced concrete owing to the limited supply of timber poles. The poles are cast in three-piece wooden molds and range from 20 feet to 35 feet in length, with a diameter ranging from 6 inches at the top to 10 inches or 13 inches at the bottom, depending upon the height of the pole. The poles are octagonal in shape, and have a hollow galvanised iron core, consisting of a pipe ranging from 6 inches in diameter at the base to 2.5 inches at the top. They are reinforced with 4, 6 or 8 bars. The cost of making these poles in sizes of 20, 25, 30 and 35 feet is $2.43, $3.85, $5.26, $7.57 respectively. Cedar poles of the same sizes would cost respectively $2.05, $3.85, $6.65 and $10.20.

Science

Daylight-saving in British Columbia.—The latest part of the world to fall a victim to the daylight-saving fallacy is British Columbia, where the provincial legislature has been petitioned to advance the standard time now in use one hour from the first Sunday in April to the third Sunday in October. In support of this petition it is stated that British Columbians now sleep during three hours of daylight in summer.

Aniline Dyes in Persian Carpets.—It is believed that about 70 per cent of all carpets now woven in Persia contain at least some aniline colors. The Persian government some years ago prohibited the use of aniline dyes, in order to maintain the prestige of the carpets made in that country, but now merely imposes a tax of 6 per cent on the value of exported carpets in which these colors are used. The United States is believed to be the largest purchaser of Persian carpets.

The Marine Meteorological Charts heretofore published monthly for each of the oceans and for the Great Lakes by the U. S. Weather Bureau have been discontinued, and hereafter the only charts of this character issued by the Government will be the Pilot Charts of the Hydrographic Office. The Weather Bureau will, however, continue to collect meteorological log-books from mariners all over the world and to work up the valuable data they contain, subsequently turning the digested material over to the Hydrographic Office for use on the charts.

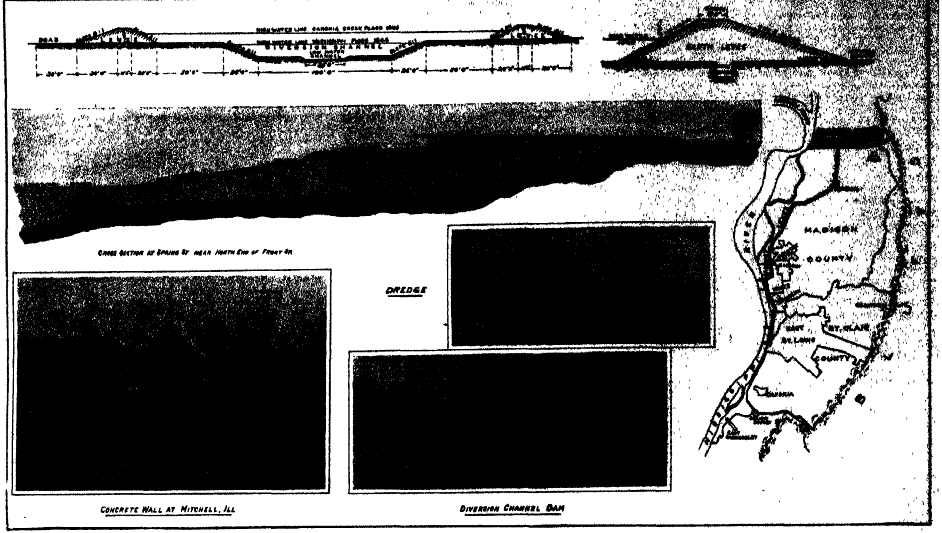
Soot-fall Observations in England.—As a result of the Smoke Abatement Conference held in London in 1912, and of the permanent Committee for the Investigation of Atmospheric Pollution, regular and systematic observations of soot-fall were begun October 1st, 1913, in the various London boroughs and 12 other important towns and cities in Great Britain with the standard instruments devised by the committee. Bailie W. B. Smith, who has charge of this work in Glasgow, recently visited the United States and endeavored to interest the municipal authorities at various places in this country to undertake similar observations.

Newspaper Botany.—Monsieur Jourdain had been talking prose all his life and never knew it until his professor told him. A certain Congressman, a couple of sessions back, immortalized himself by asking, "What are mammals?" And now Miss Lurana Sheldon and the literary editor of the *New York Times* (to say nothing of the exchange editors of the newspapers—among them the *Washington Post*—which have copied Miss Sheldon's poem without a *sic* after the word "fungus") are responsible for giving botanists a severe shock. The poem is entitled "Mistletoe Vows," and opens with the following stanza:

> "Vow to me now,"
>   Said the innocent lover;
> "Vow to me now!"
>   Boldly he glanced at the fungus above her—
> The mistletoe bough.

The museum of newspaper bulls has not received a more piquant addition since *Leslie's Weekly*, a few months ago, referred to the late Alfred Russel Wallace as "the distinguished English caricaturist."

Bradley Land: Dr. Cook Redivivus.—In an interesting and plausible little book lately published by Mr. Edwin Swift Balch, "The North Pole and Bradley Land," an energetic attempt is made to rehabilitate the character of Dr. Frederick Cook and to prove that he may, after all, have been the first man to reach the North Pole. The main points in this contention are that (1) no one has proved that Cook did not reach the pole, and most of the arguments tending to discredit him have been more or less irrelevant; (2) Cook's description of the physical conditions encountered in high latitudes tallies strikingly with Peary's; and (3) Cook's detailed account of a previously unknown land, to which he gave the name of "Bradley Land," needs only to be confirmed by some future expedition (e. g., Macmillan's or Amundsen's) to furnish a strong argument in support of the veracity of his whole narrative. Cook's "Bradley Land" lies considerably to the north of Peary's "Crocker Land," which Macmillan's expedition is hoping to rediscover and explore. Both lands were sighted at a distance by their discoverers, but not visited. Cook describes the new land, seen from his line of march, as giving the impression of two islands, though they may be part of a large land extending far to the west. Along its southern coast the land had an irregular mountainous sky line, and was perhaps 1,800 feet high. Farther north its upper surface was flat and mostly ice capped, rising in steep cliffs to about 1,200 feet. Mr. Balch points out that the verdict of the University of Copenhagen, which has militated so strongly against Cook's claims, was merely "not proven," that the ascent of Mount McKinley by Cook can never be proved or disproved, and that "from time immemorial travelers have been called liars."



Protecting East St. Louis against floods. Plan of district and details of the channels and levees.

Protecting East St. Louis Against Floods

How a Large Industrial Center Was Rendered Permanently Secure Against Inundation

By Tampton Aubuchon

THE East Side Levee and Sanitary District of Illinois extends about thirty miles along the Mississippi River, and is bounded on the east by a chain of bluffs. Within the area is a large industrial center. The principal city in the area is East St. Louis, which has a population of 80,000. The area is comparatively low and the Mississippi River formerly spread itself over a large portion of it. Through the area runs a stream called Cahokia Creek. Lying northwest of the area is a two hundred square mile plateau, which forms a water-shed for Cahokia Creek. Practically all of the waterfall of the plateau was formerly carried through the lower area by the Cahokia Creek to the Mississippi River. In the event of a heavy rainfall water from the plateau would augment the drainage of the lower area, and the Cahokia Creek would overflow its banks in the lower area High water in the Mississippi River and the Cahokia Creek would frequently occur at the same time. The Mississippi River water backing up into the channel of the Cahokia Creek would meet the downward rush of the water from the plateau and the result would be a disastrous overflow. The Mississippi River inundating the area from the west and the Cahokia Creek overflowing in the central part furnished enough water to almost submerge the area. These overflows occurred frequently and caused great inconvenience to traffic and devastation of property.

The Diversion Channel and Flood Gates.—The problem of harnessing the troublesome Cahokia Creek was partly solved by the Diversion Channel which relieves the lower area of the drainage of the plateau. At the mouth of the Cahokia Creek flood gates have been built to prevent the Mississippi River from coming up into the Cahokia Creek Channel. The Diversion Channel prevents overflow from the north and the flood gates prevent overflow from the south To protect the area against the high water of the Mississippi River the engineers have built a levee 31 miles long and seven feet higher than the flood record of 1903, which was 38 feet.

Let us begin our tour of the levee work at the extreme northern point. About where the Cahokia Creek emerges from the bluffs we find the Diversion Channel, 100 feet wide and 20 feet deep, taking the headwaters of the Cahokia Creek westward by a direct line to the Mississippi River. On both sides of it are clay dykes ten feet high. It absolutely eliminates all danger of overflow from the rainwater of the plateau. The clay dyke on the north side of the channel was built there to prevent overflow and the clay dyke on the south side of the channel is the north levee of the area.

At a distance of four miles from the head of the Diversion Channel we find a dam over which the water plunges to a level seven feet lower. On each side of the dam for a distance of about 250 feet the banks are protected with a facing of concrete and rip rap two feet thick.

The purpose of the dam is to check the flow of the water. The water which is now passing through the Diversion Channel for a distance of four and one half miles, formerly traveled about thirty miles through the lower area to the Mississippi River. The level of the bed of the Diversion Channel at its head is about twenty-five feet higher than the low water level in the Mississippi River, so that the water in the channel traveling four and one half miles, if it were not for the dam, would be falling at a rate of about five feet to the mile. Water falling at a rate of five feet to the mile is moving along at a dangerously high speed—a velocity which causes a stream to eat away its banks, undermine bridges and indulge itself in many disastrous pranks. To prevent such a condition of affairs the engineers have built the dam so as to allow the water in the Diversion Channel to have a fall of two feet to the mile. Thus the destructive head-waters of the Cahokia Creek reach the Mississippi River without tearing things asunder on their way.

Leaving the Diversion Channel, we start south and notice that the river front levee is about a mile and a half from the Mississippi River. There is no engineering reason for building the levee so far from the river at this section. The property owners in that territory which lies west of the levee did not care to bear their proportion of the expense of the levee work, so the levee was built along the least expensive route, which is back of their property, leaving them exposed to the Mississippi River high water. At Mitchell we pass a concrete wall, five feet wide at the bottom, two feet wide at the top, five feet high and one quarter of a mile long.

Leaving Mitchell we go westward to a point opposite Chouteau Island. Here the levee turns to the southwest. We move southwest until we reach Venice, where the levee approaches the river front. Provision had to be made for the drainage of the towns of Granite City, Venice and Madison. During high water the drainage of these towns is pumped across the levee through a concrete sewer. The water supply of Granite City, Venice, and Madison is pumped through pipes which run under the levee. To guard against any damage to the levee which might result from the bursting of those pipes a concrete jacket was built around that section of them which is immediately under the levee.

The drainage of the roads along the inner side of the levee during low water is conducted through the levee through automatic flood gates. The automatic flood gates hang vertically and operate like a transom. When the Mississippi River is high, its pressure being greater than the pressure from within, closes the gates. When the river recedes the drainage water presses against the gates and opens them. So far we have noticed that the levee is almost entirely made of clay, and we see the blue grass growing plentifully on both banks. Later the entire levee will be faced with concrete. In the meantime, the inhabitants of the area enjoy flood protection.

At Chouteau Island we turn to follow the levee southward. The levee reaches the river front at the Merchants Bridge. The Merchants Bridge approach is utilised as a part of the levee scheme. That side of the approach which is exposed to the current of the river was armored with a heavy facing of concrete. Just south of the Merchants Bridge approach the engineers have protected the levee with a heavy facing of rip rap. If the levee were not thoroughly protected at this point it would be likely to be badly damaged if not washed away during high water.

South of the Merchants Bridge the levee is faced with a semi-metallic substance, called slag, which is obtained from the steel foundries in the neighborhood without cost. The action of the elements upon the slag and foundry sand mixture causes it to pack and forms a solid mass with a hard surface.

As we go south we see a dredge anchored in the river and a large pipe floating on steel pontoons. Projecting out of the water at a considerable distance from the shore we see two rows of piling. These mark the new shore line. Back of the levee at this point the district board and property owners are raising the [illegible] acres of ground about 25 feet. They are doing it by means of an electrically operated dredge, equipped with a [illegible] centrifugal pump driven by a 1,000 horse-power motor.

As we move southward we come to the concrete levee in front of the principal city, East St. Louis. A new shore line is being established in front of East St. Louis, and the dredge which is now working [illegible]

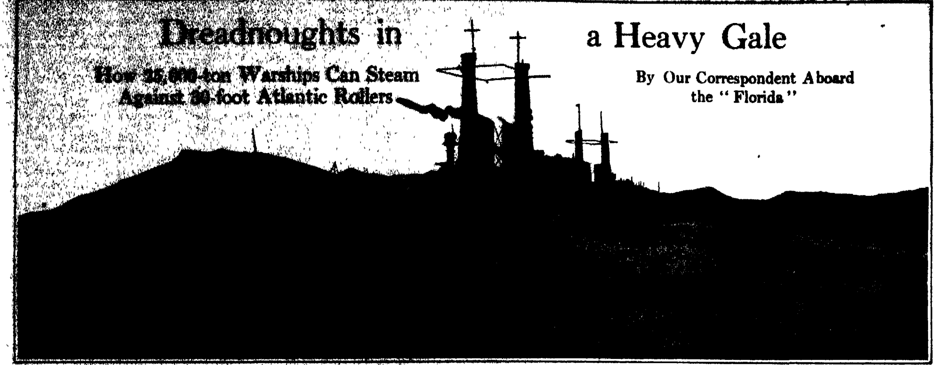
Dreadnoughts in a Heavy Gale

How 25,000-ton Warships Can Steam Against 30-foot Atlantic Rollers

By Our Correspondent Aboard the "Florida"



IT is the weather element among the many that combine to make up the efficiency of a battleship which is discussed in the present article. The subject is particularly timely as there is a strong probability that Congress will authorize two, or, perhaps, three dreadnoughts this year and the performance of these types under all conditions, but especially in rough weather, is closely watched and studied by naval constructors with a view to bettering the same design in the future.

This type of battleship was put on trial during the homeward passage of the Atlantic fleet from the Mediterranean, where it had been visiting various Italian and French ports. About one thousand miles from New York the fleet encountered a storm, which, for 24 hours, buffeted these great ships about as though they had been mere toys. At one time during the storm the wind was blowing at a rate of 90 miles an hour, and the sea was running so high that it was considered on the flagship whether it was not advisable to deviate the ships from their true course so that the immense waves would not be taken head on.

Never before had the dreadnoughts met with such weather, and even the blow encountered off Hatteras in 1912, which scattered the fleet and delayed it for several days, was mild in comparison. Some of the old, experienced men even went so far as to call the storm a typhoon. Rear Admiral Charles J. Badger, commander in chief of the fleet, ordered it to head into the teeth of the storm at a speed of 12½ knots, which, because of the friction of the wind and waves, was reduced to about 9.

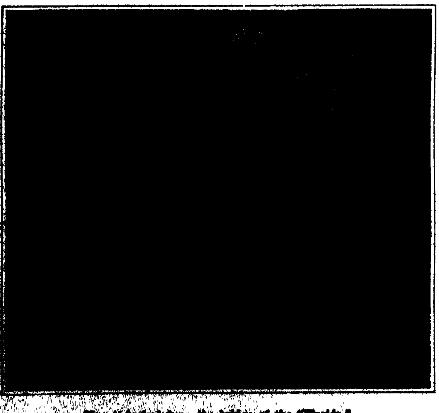
The dreadnought "Florida," upon which I was a passenger, was third in line. The "Arkansas" and the "Utah" were ahead; the "Delaware" was behind, and the "Wyoming" and "Vermont" were some five miles to the south'ard. During the most violent part of the storm the "Vermont" was disabled by a broken propeller shaft and the "Delaware" went to its assistance.

As the storm was heralded by dangerous "mares' tails" and a rapidly falling barometer, everything was battened down and secured. All hatches were dogged down, the deck ventilators closed, and an extra turn taken on the dogs of the gun ports. We turned in hardly knowing what to expect.

A succession of deafening crashes at the bows awakened everyone in the officers' quarters at about 5 o'clock in the morning. The ship was pitching and straining terribly, the air below decks was already becoming foul and for the first time I felt "squeamish." A bath would have helped some, but the forward compartment had several inches of water on its deck, and with every pitch and heave more water would find its way through the ventilators [illegible] through the [illegible]

Rising to a big sea.

The "Utah" throws a sea from her flaring bows.



How it looked from the bridge of the "Florida."

reached the bridge, which, high as it was above the water—about fifty feet—was enveloped in solid sheets of green water tossed high by the bow and hurled aft at express train speed. It was simply impossible for a man to stand the force of the wind and water as it drove across the bridge. By watch time, by stadimeter measurement, the crests of the waves were something more than a quarter of a mile apart.

The bow of the "Florida" was smashing up and down at a rate of five times a minute, reaching limits of vertical rise and fall nearly fifty feet apart. During the first thirty feet of the drop the force of gravity had full sway. The flare of the bow caught the sea and for an instant checked the drop only to lose its hold an instant later, when down went the bow again for twenty feet more. As the bows of the dreadnoughts are very pointed with a flare at the top, there was but little resistance furnished against the first period of downward drop.

With her deck at an angle of ten degrees to the horizontal, the "Florida" mounted the great waves. They passed under, leaving the bow high in the air. At times, more than thirty feet of the ship's bottom at the stem was out of water. Of course something more than air is needed to support a body weighing nearly 22,000 tons, which is about the displacement of the "Florida." The "Wyoming" and "Arkansas" class are several thousand tons heavier, while the new "Pennsylvania," now building, is a ship of 31,000 tons displacement.

I cast about for something with which all civilians are familiar to illustrate the severe motion of the ship and the experience through which the ships passed. Just enter one of the fast elevators which shoot from the basement of a skyscraper to the roof in such incredibly short time. Let the elevator drop suddenly for thirty feet. The floor seems to fall out from under the feet of the passenger and he feels almost light enough to fly. Let the elevator pause and one feels as though he were going through the floor, and just as the thought flashes through his mind that he's glad the drop is over, down goes the elevator again, with lightning-like rapidity, for fifteen or twenty feet. It stops with a convulsive shudder and then starts upward again with a jerk. About this time, to get the whole effect, someone should pour a torrent of water down the elevator shaft. Repeat this performance, and add to it a deafening noise so that conversation is impossible, five times a minute for 24 hours, and you have a suggestion of what the ships of the Atlantic battleship fleet went through.

Plunging through such a sea was the acid test of the seaworthiness of the dreadnought type, and the United States can now feel assured that the dreadnoughts can steam at their standard speeds through any sort of weather.

Even in the roughest part of the storm

the battleship "Florida" would have been able to go into action. The forward turrets were awash, but the three after turrets could have been used with a fair degree of success against an enemy several miles away. It has long been contended that a naval battle could not be fought in very rough weather I believe that this contention has been disproved, for during the worst of the blow the guns of the "Florida" were trained on the flagship "Wyoming," five miles on the port beam, and two of the pointers told me that they had no difficulty whatsoever in keeping on the target.

A number of defects in the construction of the great dreadnoughts seems to have occurred; this is not a one-man opinion, but the consensus of opinion of the naval officers in the Atlantic fleet.

The gravest defect is the placing of the secondary battery of five-inch guns, which are supposed to be used for torpedo defense; that is, to drive off torpedo boats. The guns on the "Florida" type of ship are on the gun deck and but fifteen feet above the water. Gun ports, a part of the sides of the ship, must be opened if the guns are to be used.

Even in moderate weather these gun ports may be opened only at the grave risk of flooding the various compartments of the ship. This, of course, would short-circuit the electrical apparatus and render the guns hopelessly useless.

Torpedo destroyers are being built larger and larger. There is hardly any ordinary gale that hinders their operation. Certainly there were many days and nights when the five-inch guns of the "Florida" could not have been used, although the weather was mild enough to permit destroyers to operate with a reasonable probability of success. It would be under these conditions that a clever strategist would send in his destroyers to torpedo an enemy's fleet. The only defense that the "Florida" type would have, would be the great 12-inch guns.

Either these guns of the secondary battery should be placed on a higher deck or should be removed entirely, thus reducing the tonnage by many hundreds of tons. The ordnance experts state that if the secondary battery is placed on a higher deck where it can operate in any sea in which a destroyer can operate, the center of gravity of the ship will be disturbed and that the guns would have to do without armor. Armor may or may not be of great importance for the protection of the secondary battery; but as it is placed now, the secondary battery, under heavy weather conditions, is practically useless for the purpose for which it is intended. The larger the destroyers become (and they are growing in tonnage each year by leaps and bounds) the more useless becomes the secondary battery; for, the larger the destroyer, the greater the seaway in which she can operate.

Considerable difficulty has been experienced in lashing the anchors for sea. The bill-board type of anchor has been abandoned, and on the dreadnoughts the anchor chain is drawn taut by the anchor engine and is secured. The anchor itself is not lashed by chains and ropes with the result that sometimes it works loose and in a heavy sea will batter the ship's side unmercifully. The anchor of the "Florida," which weighed several tons, worked loose during the gale, and, with every heave of the ship, would batter the hawse pipe.

The experiment of placing the officers' quarters forward under the forecastle is condemned by nearly every officer in the fleet. The motion is so severe that they cannot do the work which must be done in their rooms, and, when at sea, the wardroom, cut off from the rest of the ship, is so stuffy and uncomfortable as to be unbearable.

On the "Florida" there were two five-inch guns in the wardroom. It was impossible to tightly close the gun ports, with the result that several times the officers dined with an inch or two of water on the deck.

On the whole, the dreadnought type of ship has shown its absolute superiority over all other classes of craft for main line-of-battle position The motion was severe; but at no time would it have been impossible to go into action at five minutes notice. The ability of the ships to maintain a standard speed through any kind of weather will, of course, have an important bearing on any naval actions into which the dreadnought type may be ordered. It is probable that in the dreadnoughts to be built in the future some change will be made in the disposition of the secondary battery; but it is certain that so far as the general design is concerned the type will be standard for many years to come. As to the lines of the ship and the great tonnage found in the newer dreadnoughts, no change will be made until great strides have been accomplishd in the art of marine construction; for the type is as nearly perfect as possible.

The Symons Gold Medal of the Royal Meteorological Society awarded every two years, and alternately to a British and a foreign meteorologist, will be presented at the annual meeting of the Society next January to Mr. W. H. Dines, F.R.S., the leading English student of the upper air.

The Most Needed Invention

To the Editor of the SCIENTIFIC AMERICAN:

The most needed invention, the writer believes, is a means of harnessing electricity in its transit from heaven to earth in sufficient quantities to be of practical use for power, heat, and light. Benjamin Franklin, before we were born, harnessed a sufficient quantity of it to produce a spark, and it seems that all of our inventors since then have failed to do more in that line.

The writer believes this as sure to come as that we have the telephone and wireless telegraph and aeroplane. Wonders never cease. It is as it were but a fortnight since the idea of an aeronaut flying head down, looping the loop, and even defying the skill of the birds, who have been supreme in the air all the past centuries. Let the minds of our inventors center upon the harnessing of the boundless electric forces and see how soon advancement will be recorded.

Indianapolis, Ind. J. A. MCANULTY.

Student Labor and Public Works

To the Editor of the SCIENTIFIC AMERICAN:

I noticed in the SCIENTIFIC AMERICAN for December 6th a short article on student labor on public works. The Dickinson County High School has been employing students in various occupations for the past two years. The high school has a farm and a school garden. A part of the labor on these has been performed by students. The mechanics department of the institution makes hay racks, water troughs, feed troughs, singletrees, doubletrees, neck yokes, wagon tongues, etc., for the farmers of the surrounding country. It also repaired last year two gasoline engines. A new shop for iron work is now nearing completion. All of the wood work, including the making of the window frames, doors, roofing, etc., has been done by student labor. The cement floor and walks will also be put in by students W. S. ROSS.

Chapman, Kans.

A Comparison of Battleships

To the Editor of the SCIENTIFIC AMERICAN:

Your article in the SCIENTIFIC AMERICAN SUPPLEMENT of November 22nd comparing so-called contemporary British and American battleships is a little unfair to British designers and not up to the usual SCIENTIFIC AMERICAN standard of accuracy. As the British and American fleets can never, by any conceivable circumstances, be arrayed except on the same side, I think you will agree that the facts can be discussed and compared openly and without fear, and I hope you will allow me briefly to refer to the matter. You compare the "Nevada" and "Orion," but I cannot imagine how you can consider this a fair comparison seeing that the "Orion" was actually afloat in 1910 and completed in 1911, while the "Nevada" will not be ready until 1915.

I presume you select the "Nevada" as being as powerful a battleship as you have launched; and if you wish for a contemporary British ship of the same date and most powerful type, you will find her in the "Queen Elizabeth."

These two fine ships compare as follows:

	"Nevada."	"Queen Elizabeth."
Date of launch	1913	1913
Date of completion....	1915	1914
Tonnage	27,500	27,500
Thickness of armor belt	13½ in.	13½ in.
Designed speed	20½ knots	25 knots
Armament	10—14 in. 21—5 in.	8—15 in. 16—6 in.
Weight of broadside...	14,000 lbs.	15,600 lbs.
Fire direct ahead or astern	7,000 lbs.	7,800 lbs.
Torpedo tubes	4	5

Of these two boats launched at the same time, of identically the same tonnage, the "Queen Elizabeth" is inferior in no particular and decidedly superior in many. H. ALLAN MORGAN.

Holmwood, Knutsford, Cheshire, England.

The Velocity of Wireless Waves

To the Editor of the SCIENTIFIC AMERICAN:

The scheme for measuring the velocity of wireless waves proposed by Mr. Riggs in your issue of November 15th, strikes me as very interesting and ingenious, but I think that the problem is even simpler than he indicates. His proposal is that clocks at the Paris and Arlington stations should send out signals each second and that these should be received on chronographic recorders. Why not have the signal sent from one end and echoed back from the other as soon as convenient afterward, with the record made at each end of the time elapsed between sending and receiving? Thus, suppose the Paris operator sends first and the Washington station answers within half a second. The return would be received at Paris after an interval equal to the delay at the other end plus twice the time required for the travel of the wave.

It is possible to anticipate approximately the determination of the time of transit. Hertzian waves are undulations of the same ether which carries the radiations of light and heat. The speed of the latter waves has been measured many times with considerable accuracy, and is close to 186,000 miles per second. Radiant heat, light of various colors and the invisible ultra-violet radiation differ among themselves only in wave-length. The speed is the same for all, and all are of the same type, namely, transverse vibrations like those on the surface of water. It appears that wireless waves are of exactly the same kind, but thousands of times longer than the minute fractions of an inch which measure the length of light and heat waves.

From Paris to Washington it is approximately 4,000 miles. At 186,000 miles per second, this means that the signal will reach Washington about 0.022 second after leaving Paris.

For recording intervals of time so short as this with accuracy worthy of the opportunity, the ordinary chronograph would seem hardly suitable. It occurs to me that a photographic appliance might be devised to do the work a great deal better. Some such arrangement, for example, as this: A circular sensitive plate rotated at high speed in a light-tight case containing a small window which gradually travels radially. A weak constant light traces through the window a spiral line on the plate. The receiver of the wireless wave actuates a small mirror which throws an intense beam of light across the window at every vibration, but normally the beam strikes the case at one side of the opening. The same instrument might act to record the sending of the signal, or the light of the spark itself coming through the window could make the mark. Then, knowing the speed of rotation of the plate, or having photographic marks made at suitable intervals of time along the spiral, the determination of the lapse of time would be easy.

A weak impulse which had traveled 4,000 miles should be much more positive in its action upon some such delicate apparatus as that needed to deflect a tiny mirror than upon a machine which could make a mechanical mark upon a paper record. The device to actuate the mirror might be some sort of D'Arsonval galvanometer, or perhaps even a telephone receiver with the mirror glued to the diaphragm.

Berkeley, Cal. HOWARD H. BLISS.

Lunar Rainbow

To the Editor of the SCIENTIFIC AMERICAN:

Have noticed your recent articles on lunar rainbows and rainbows seen after sunset, and it occurred to me that you might be interested in a report of a lunar rainbow observed by the writer on the night of September 18th, 1913, at 9:15 P. M.

This was observed from a Vermont Central train while running between Mount Hermon and Northfield, Mass. There was a bright moon high in the sky, and nearly full at the time. Tiny needle points of rain showed on the panes, and the rainbow was observed on the west side of the track, apparently about five hundred feet distance. The most striking features were that the southern end of the bow rested upon the pasture, while the northern end rested upon the tops of a group of trees apparently sheltering a cemetery. All the colors of the usual rainbow seemed to be present, except they were of a lighter shade.

This same bow was observed by Mr. F. H. Whitcomb of New London, Conn. JAMES W. AUGHILTREE.

New York city.

The Remarkable Long Distance Flight of Védrines

THE Paris to Cairo flight places Pierre Jules Védrines at the head of long-distance aviators. Rodgers's 4,000-mile journey from Sheepshead Bay to San Francisco in 1912 and Brindejonc des Moulinais's Paris-Warsaw-St. Petersburg-Paris round of 3,000 miles this year were easy flights in comparison.

Rodgers and Brindejonc des Moulinais flew over civilized lands. Védrines made himself subject to arrest in Germany by going outside the prescribed area, was fired on in Servia; crossed the battlefields of Thrace, and traversed mountains 16,000 feet high on his way from Constantinople.

Communication Between Aircraft and the Ground[*]

Adapting Wireless to the Requirements of Military Aircraft

By Major H. Bannerman-Phillips

RECONNAISSANCE by aircraft has now become an established and recognized necessity in military operations of any magnitude, and if thus far of supplementary value only for warfare at sea, it is nevertheless of such importance that every nation which aspires to be a naval power finds it necessary to study the subject.

It is impossible to say how far aircraft will be useful for purposes of aggression, but at present they are to be reckoned upon only for obtaining information. How to convey that information to headquarters with the least possible loss of time is frequently of as much importance as how to procure it. Aircraft travel such distances on reconnaissance that visual signaling is often impracticable, besides being liable to be read by the enemy, and at short distances it is quicker to drop written messages at pre-arranged spots or to return and report in person.

It is of course feasible for the observer who is responsible for the results of the reconnaissance to descend from an airship by means of a parachute at a given point, say near the headquarters staff in the field, the vessel which carried him being then free to proceed to the air service camp to refit, without loss of time. Major Maitland, an officer of the British Royal Flying Corps, proved this on October 18th last by dropping from the airship "Delta" in a parachute by way of experiment when at an altitude of about 2,000 feet with complete success. He had dropped from a balloon on a previous occasion, in similar fashion.

The Possibilities of Wireless.

Wireless telegraphy therefore is the best method of sending messages, although it is open to the objection that its use may betray the presence of the scouting aircraft to the enemy, especially at night, when it might otherwise escape notice in the case of an airship. The weight of the apparatus is another matter which is a disadvantage and which practically reduces its use on aeroplanes to comparatively short distances. Then again since wireless messages are liable to be picked up and read by the enemy, it will usually be advisable to send them in cipher. This involves loss of time spent in de-coding them, and time is nearly always precious when there is a question of conveying information, as already pointed out. Therefore it may be simpler, quicker and altogether more satisfactory, especially in the case of an aeroplane, to return to headquarters with the results of a reconnaissance, than to code and send it and have it de-coded at the ground receiving station, whence it may have to be again sent on by messenger or signal to headquarters.

Even in the case of code messages, the enemy may possess officers skilled in cryptography who will be able in a reasonable time to discover the code and read them.

The aeroplane in its present state of development is at a considerable disadvantage as compared with the dirigible in regard to the use of wireless telegraphy. The continuous vibration and noise of engines and propeller render it impossible to receive any message whatever,[†] and unless it carries an observer as well as a pilot, the sending of anything more than the very simplest report would be out of the question. Considerations of weight and aerial militate against sending farther than about thirty miles, and if it is considered necessary to carry an observer, oil and fuel for long-distance flight, camera and possibly an automatic rifle and supply of ammunition for defensive purposes, the additional weight of wireless apparatus will become a very serious consideration. It would be also a doubtful advantage in view of the time to be taken in sending messages by code when a return can be made at 50 or 60 miles an hour for the purpose of reporting direct to headquarters.

With the airship or at any rate with the large weight-carrying airships, the case is reversed. To begin with, messages can be sent up to 200 miles, either to a permanent coast or other station, or to a cart-station such as those of the Marconi Wireless Telegraph Company, specially designed for military work. It is quite feasible to stop the engines for a time in order to receive instructions on the subject of the reconnaissance in answer to reports sent. According to present rates of speed an airship could cover the 200 miles of the outward journey in four to five hours, and after hovering or sailing slowly for an hour or so over the area to be reconnoitered (while simultaneous notes were made by different observers and photographs taken), could return in another four or five hours with the negatives developed and ready to supplement the reports. In the meanwhile these latter would be sent on ahead by wireless at once, and corroboration, personal explanation and answer to questions concerning details would follow on arrival at headquarters.

Flashes and Their Utility.

Methods of visual signaling between aircraft and aircraft in mid-air or between aircraft and the ground, include flashing lamps at night from either aeroplanes or airships, and semaphore from the latter by day. Written messages can be dropped by parachute. Where it is inadvisable to return and report, direct wireless telegraphy is by far the best of all methods of communication. Any wireless system which can be worked on land answers practically as well in mid-air, though of course the weight to be carried is a very important consideration and makes certain systems unsuitable.

The British Air Service has its own system, and the Rouget is also much used. A satisfactory aerial for aircraft is the trailing wire which can be kept rolled upon a drum and unrolled and rolled up again when not in use. A safety catch can be arranged in connection with this form of aerial, so that if by accident it should become entangled in anything during flight, the pull would release it and thus obviate damage.[*]

With regard to portable ground stations to be used in communications by wireless with aircraft, it would take too long to compare the merits of different systems. It must suffice to give a short description without too many details, of some of the best known—those of the Marconi Company, who have made a special study of the type. The largest of these stations has a range of about 200 miles. It is designed for wheel transport, the time required to erect or dismantle is 20 minutes with 8 men; 3 men could do the work, but it would take longer, naturally. The weight of the station alone is about 784 pounds. For transport it is normally divided into two horse-drawn units, or the whole can be conveyed as one unit, if self-propelled. In the former case the limbered wagon type of vehicle has been adopted. The first limber carries the generating plant and the wagon carries the transmitting and receiving apparatus; the second limber carries a supply of gasoline and spare parts, and the wagon carries the masts with all their gear, as well as the aerial and earth wires. The prime mover of the station consists of a 2-cylinder gasoline engine having an output of about 8 horse-power. It runs at a speed of 2,000 revolutions per minute, and is air-cooled by a special blower mounted on the flywheel, which keeps a continual blast of air circulating round the cylinders.

The engine is direct coupled on an aluminium bed-plate to a self-exciting alternator having an output of about 2 kilowatts. Mounted on the shaft of this alternator at the end remote from the engine is the disk discharger, the function of the latter being to break up the train of waves into groups of waves so as to give the sound produced in the receivers a musical note. The current from the generator is carried by a flexible cable to the instrument cart, where it passes through the manipulating key to the transformer. Here it is transformed to a high voltage current which charges the battery of condensers in the primary high-frequency circuit. These condensers discharge themselves through the disk discharger (already mentioned) and through the primary of the high-frequency transformer, the secondary of this high-frequency transformer being connected to the aerial on one side and to the earth on the other side.

Both the primary and the secondary circuits of this high-frequency transformer are connected through suitable inductances for changing the wave-length, and through the change-time switch, by means of which the operator is able to change his wave-length at will. The receiving apparatus is also carried in this cart and consists of 2 separate receivers, one receiver being specially adapted for the change-time switch, and the other receiver being of a more simple type and arranged for tuning up quickly to any wave-length between 500 and 1,400 meters.

The antenna consists of 2 woven wires about 500 feet long, which are supported by 2 masts 70 feet high. These masts are carried in sections and erected by means of a derrick built up of 2 mast-sections.

When it is necessary for a mobile wireless telegraph station to be carried by pack transport the engine and dynamo are mounted on either side of a rigid pack-saddle frame adjustable to suit different sized animals. The saddle frame acts as a bed-plate for the generating set, and to remove the saddle from the back of a horse and get the station into operation takes only one minute. This type of saddle is used to carry all the four loads of the "Cavalry Station," which can move at a gallop, if required.

An even lighter station, but with a range of only 10 miles, called the "Knapsack" station, can be transported by 4 men, who each carry a load of 20 to 30 pounds, strapped to their backs. This would be useful in connection with aircraft principally in mountainous country.

---

[*] The cover design of this week's issue of the SCIENTIFIC AMERICAN represents a type of portable, wireless apparatus which has been designed by Mr. William Dubilier of New York for use on aeroplanes, and which has proven itself remarkably efficient in tests conducted at Aldershot last autumn by British army officers. The apparatus overcomes the principal objections mentioned in Major Bannerman-Phillips article. For the benefit of those familiar with wireless it may be stated that in Mr. Dubilier's apparatus sine waves of a musical frequency are produced for the first time from continuous current without the use of a rotary converter. An apparatus of 250 watts capacity weighs only 20 pounds complete for transmitting, without the generator, which itself is not larger than an ordinary fan motor and weighs 16 pounds. The principle of operation depends on obtaining a series of unidirectional impulses by a condenser discharge, pulsating currents following one another at regular intervals at a frequency of 500 per second. These impulses are produced from a primary direct current. It is possible to produce any frequency up to 1,000, the apparatus weighing complete not over 40 pounds and having an over-water range of about 250 miles on shipboard. An instrument weighing 15 pounds and occupying a space of less than one third of a cubic foot transmitted signals 30 miles to a portable aerial in tests conducted by the British government.—EDITOR.

[†] It has been [illegible] possible to receive signals visually by [illegible]. This would obviate the difficulty [illegible].—EDITOR.

[*] Our cover design shows how the aerial may be disposed on the wings.—EDITOR.

The Lobster and Its Eggs

THE way in which the lobster carries out its transformations from the egg to the adult stage has been most obscure up to the present time, but the problem may now be said to be solved by the researches made by Prof. Bouvier of the Paris Natural History Museum. These he carried out at the Plymouth maritime laboratory which is well fitted out for the purpose; the character of the coast is such that the lobsters are abundant among the rocks surrounding the lighthouse and they tend to remain at this place. After hatching, the young have an entirely different form from what we know, and in the larval state they are quite transparent. The body has three pairs of swimmers and is flat like a leaf, hence the name "phyllosoma" which is given them. Of very minute size, they live entirely in the water. No less than nine stages of transformation are observed between the larva and the perfect state, but the larva could not be cultivated up to the present. On the other hand, there were a few rare specimens found of what is known as "puerulus," considered by some as one stage in the evolution, but this was not certain. Prof. Bouvier now proves this to be a fact, and it represents the lobster at the time when it ceases to swim and takes up its lodging in the rocks. At this time it is about an inch long and quite transparent, with a rather soft shell. As it is hard to see or to capture, but few specimens exist at Paris, London, and others places. However, a fortunate catch at Plymouth brought up a "puerulus" which was being transformed into a lobster, so that the proof is now complete. It is stated that the time for the evolution from hatching of the larva up to the perfect lobster form is only two months.

Substitutes for Celluloid

THE increasing use of celluloid for the manufacture of imitation ivory, horn, shell, linen, wood, glass, porcelain, etc., is due to the cheapness of this mixture of pyroxylin and camphor. It has, however, the serious drawback of being highly inflammable, and even explosive at high temperatures.

Hence substitutes lacking this dangerous property have long been sought. Such a one is acetyl-cellulose, made by the action of acetic acid on pure cellulose. This, however, is more costly, and therefore has not made its way except where price is a secondary consideration.

Very recently, however, substitutes have been invented which are not only effective, but cheap. These are *viscose* and *formyl-cellulose*, already known because of their employment in making artificial silk.

While they are not as yet utilizable for objects which must have great solidity like those of horn and ivory, it is safe to predict a great future for them, since already blocks of *viscoid* have been produced which can be readily colored, polished, and worked.

Morning and Evening Stars for 1914

A Transit of Mercury

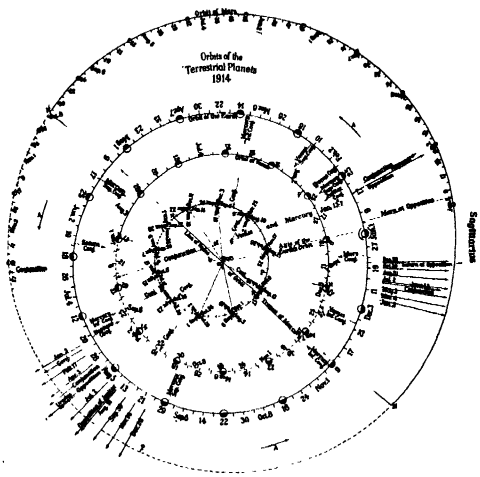
By Frederic R. Honey, Trinity College

THE purpose of this annual paper is to show how morning and evening stars may be determined by inspection of the accompanying plot, and at the same time to exhibit graphically the principal elements of the solar system, to the end that the reader may familiarize himself with the relative positions of all the planets at any time during the year. Anything beyond a general inclusion of the asteroids has been avoided, inasmuch as these eight hundred little bodies occupying the space between Mars and Jupiter, would require a separate article for extensive treatment.

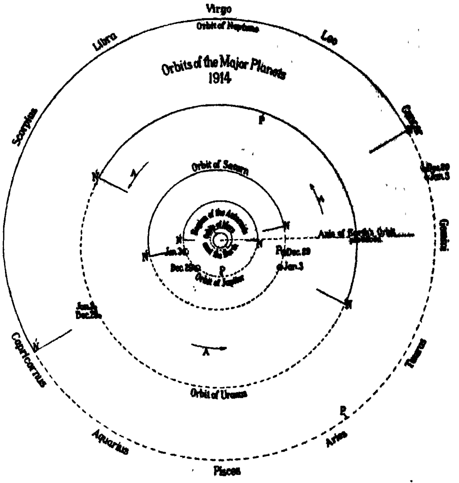
The year 1914 includes in its record the interesting departure from the usual, in a transit of Mercury which occurs in November of this year, when a tiny speck representing a planet 3,000 miles in diameter will traverse a chord of the Sun's disk, accomplishing the journey in a little over four hours.

The Sun.

The Sun, which controls the motions of the planets, is a self-luminous globe whose diameter is 864,367 miles, or a little over one and eight tenths the diameter of the moon's orbit. Its volume is 1,300,000 times the Earth's volume. The Sun rotates on its axis, which is inclined to the ecliptic, in about twenty-five and a quarter days, and in the same direction as the revolution of the planets in their orbits, as illustrated by the arrows *A* in the plots of the orbits of the major and terrestrial planets. The Sun's apparent diameter, which subtends an angle of a little over ½ degree, varies, slightly during the year. It subtends a maximum angle when the Earth is at perihelion in January; and a minimum angle when the earth is at aphelion in July.



The orbits of the terrestrial planets for 1914.



The orbits of the major planets for 1914.

The Terrestrial Planets.

The planets revolve around the Sun in the same direction in elliptic orbits, with the Sun at one focus, conforming to Kepler's first law of planetary motion. The orbital planes are inclined at small angles to the ecliptic, which is the plane of the Earth's orbit; and the intersection of each plane with that of the ecliptic is called the line of nodes. This line passes through the Sun, and in order to avoid confusion it is drawn only in the plot of Mercury's orbit. A part of this line is shown, however, in each of the plots of the orbits of all the planets at *N* and *N'*, where the planet passes from one side of the ecliptic to the other. If this page be placed in a horizontal position, it may be regarded as the plane of the ecliptic; and for convenience of reference it is conceived to divide space into two parts, viz., that which is below and above the ecliptic. *N* is called the ascending node, and *N'* the descending node; perihelion, or point of nearest approach to the Sun, is at *P*. The planets are divided into two groups of four, the terrestrial and major planets; the orbits of the latter are drawn to a scale which is very much reduced; and the great difference between the scales will be apparent on comparing the orbits of the Earth and Mars in the two plots.

The Earth.

Our planet, which may be regarded as a moving observatory, revolves around the Sun in 365¼ days at a mean distance of 92,894,767 miles, and at a mean velocity in its orbit of 18½ miles per second. The axis of the Earth is inclined to the plane of the ecliptic at an angle of about 66½ degrees, and the Earth rotates uniformly in a sidereal day, which is nearly four minutes shorter than a mean solar day, in the direction of the arrows (see position for January 1st). The center of the orbit is at *a*, which is at a distance of a little over 1,500,000 miles from the Sun (= *e*, the eccentricity). At the perihelion passage in January the Earth is therefore more than 3,000,000 miles nearer the Sun than it is at aphelion in July. The positions of the Earth and of all the terrestrial planets are shown at intervals of four days.

Mercury.

The great velocity and variability of the planet's motion, by which the perihelion and aphelion passages are made respectively at the rates of 35 and 23 miles per second, are due to the close proximity of Mercury to the Sun, and to the eccentricity of its orbit, which is greater than that of the orbits of any of the terrestrial or major planets. Mercury's mean distance from the Sun, expressed in terms of the Earth's distance, is 0.3871; and the eccentricity, bringing the center of the orbit to *b*, is a little over one fifth. In representing it on the plane of the ecliptic its true form is obviously distorted, but the deviation is scarcely apparent in the plot. The maximum angle which a radius vector forms with the plane of the ecliptic is 7 degrees, the inclination of the planet's orbit, and since the projection of a line on a plane is equal to its true length multiplied by the cosine of the angle which the line forms with the plane, the maximum diminution in the present case is less than one hundredth of its length (cos 7 deg. = 0.9925).

The planet's period is very nearly 88 days (87.97 days) and its position is shown at intervals of two days. Kepler's second law, the radius vector sweeps out equal areas in equal times, is illustrated. For example, taking the Sun's center as the common vertex of two triangles whose bases, representing equal periods of time, are respectively that part of the orbit between the dates September 6th and September 14th, and that part between the dates October 24th and November, 1st, the areas of these triangles are equal.

Since Mercury's orbit is inclined at a greater angle than that of any of the terrestrial or major planets, it is clear that the projections of the orbits of the other planets in both plots do not differ appreciably from their true form.

Venus.

On account of the small eccentricity which is scarcely visible in the plot, the orbit of Venus differs very little from a circle, and the motion of the planet is nearly uniform at the rate of 21.9 miles per second. The orbital plane is inclined at an angle which is a little less than one half that of Mercury. The planet's distance from the Sun, in terms of the Earth's mean distance, is 0.723; and the period of revolution is 224.7 days. Thus Venus makes more than one and a half revolutions during the year. On August 19th the planet returns to a point on the orbit which is very near the position of January 1st, a distance traversed in seven tenths of a day. The dates until August 5th are attached without the orbit; for the rest of the year they are shown within the orbit.

Mars.

The plane of the orbit of Mars is inclined at an angle of only 1.85 degrees. While the eccentricity is less than that of Mercury's orbit, its linear eccentricity, or actual distance from the Sun to the center *c*, which is nearly one tenth the mean distance, is much greater than the corresponding measurement on the axis of Mercury's orbit. The mean velocity is 15 miles per second; the mean distance from the Sun is 1.5237 times the Earth's distance; and the period of revolution is 1.88 years.

The Major Planets.

The following table gives some of the elements of the orbits of the major planets. The mean distances are given in terms of the Earth's mean distance.

Planet.	Mean Distance.	Period Years.	Velocity miles per Second.	Eccentricity.	Inclination to Ecliptic.
Jupiter....	5.20	11.86	8.1	0.048	1.31°
Saturn.....	9.54	29.46	6.0	0.056	2.49°
Uranus.....	19.19	84.02	4.2	0.047	0.77°
Neptune....	30.07	164.79	3.4	0.009	1.78°

In the plot of the orbits of the terrestrial planets, the positions of Jupiter as seen from the Sun are indicated by arrows at intervals of forty-five days; and Saturn's positions at intervals of sixty days. The positions of Uranus and Neptune are given at the dates of conjunction and opposition. In the plot of the orbits of the major planets, the positions are shown for January 3rd and December 29th.

A Transit of Mercury.

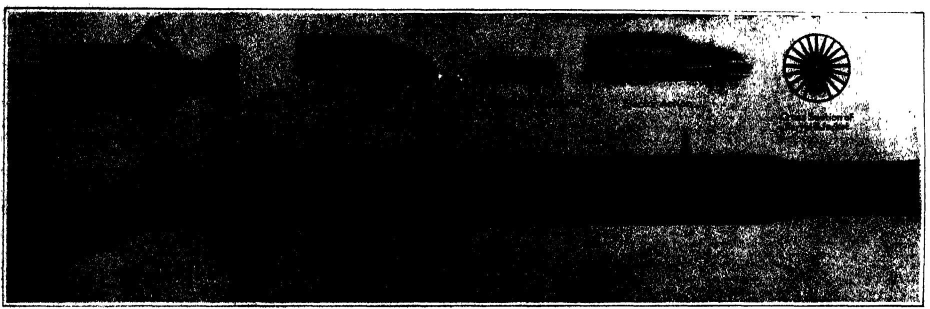
A transit of Mercury across the Sun's disk can occur only in the month of May or November, and when the planet is near one of the nodes of the orbit. If the line of the nodes be produced in both directions, it will be seen that it intersects the Earth's orbit at points which our planet reaches early in these months. On account of the great eccentricity of Mercury's orbit, he comes very much nearer the Sun at the ascending node when he is approaching perihelion; and as a consequence November transits are far more frequent than those which occur in the month of May. The intervals of time between two consecutive November transits, may be either seven or thirteen years.

Mercury's period (nearly 88 days) expressed in a fraction of a year is 0.24085; and $\frac{7}{0.24085} = 29.06$; i. e., Mercury makes a very little over 29 revolutions in seven years. Thus one transit will follow another, seven years later, provided the planet is near enough to the node at the later date; and since during this period it makes a small fraction over 29 revolutions, the [illegible] occur earlier in the month. The date of the last transit was November 14th, 1907. The date this year will be November 7th. The planet will reach [illegible] the [illegible] of the Sun's disk a few minutes [illegible] Greenwich [illegible]. Owing to the difference [illegible] between [illegible] and Washington, the [illegible] five hours [illegible] with Mercury [illegible]

[illegible] very nearly fifty-four revolutions; thus $\frac{13}{0.24085} = 53.98$; i. e., one transit may succeed another, after an interval of thirteen years, provided Mercury is near enough to the node at the second date, in which event the transit occurs later in the month. Transits occur at consecutive intervals represented by the series 7, 13, 13, 13, 7, 13, 13, 13, 7, etc. The sum of any four consecutive periods is 46 years, which always includes one period of 7 and three of 13 years. Dividing 46 by Mercury's period we have $\frac{46}{0.24085} = 190.99$. Thus, it appears that after an interval of 46 years, and 191 revolutions of the planet, a transit occurs when the Earth and Mercury are near the same point in each orbit. The following dates when transits occurred, illustrate these intervals: November 4th, 1867; November 7th, 1881; November 10th, 1894; November 14th, 1907; November 7th, 1914. The first observation of a transit of Mercury was made in November, 1631; and it will be seen that this date belongs to the series; thus 1907 — 1631 = 276 = 46 × 6.

How to Find Morning and Evening Stars.

Morning and evening stars for any day in the year may be found by placing the plot of the terrestrial planets in a position where the date attached to the Earth may be read without turning the head. In this position a straight edge through the Earth and the Sun will divide the planets into two groups; those on the right which rise before the Sun, and which are therefore morning stars, and those on the left, which set after the Sun, and are evening stars. Between superior and inferior conjunction, Venus and Mercury are evening stars; and between inferior and superior conjunction, they are morning stars. Before conjunction a planet whose orbit is outside the Earth's orbit is evening star; after conjunction it is morning star. At the date of opposition, when a planet is above the horizon before and after midnight, it is both morning and evening star. The Earth rotates in the direction of the arrows (see position for January 1st). Between sun-set and sun-rise, the observer is on that half of the Earth's surface which is in shadow. At sun-rise he emerges from it; and at sun-set he enters it. By an inspection of the plot it is a simple matter to determine the relative positions of the observer to the Sun and all the planets during the day or night, at any assigned date.



This gun, weighing only 26½ pounds and firing 800 shots per minute at maximum speed, is specially adapted for military aeroplanes.

Details of the Lewis air-cooled machine gun.

The Lewis Air-cooled Machine Gun

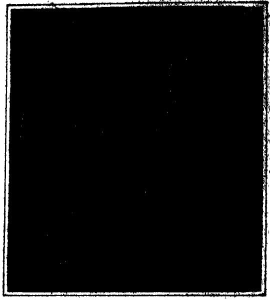
WE present illustrations of an air-cooled machine gun, the invention of Col. I. N. Lewis, formerly of the United States Army, which has been undergoing firing trials successfully in Russia, Belgium, Italy, Austria, and Sweden, and is now being tested by a special board of officers of the United States Army. Col. Lewis is known to our readers as the inventor of the Lewis depression rangefinder, which is in service on the coast defense batteries of the United States seaboard.

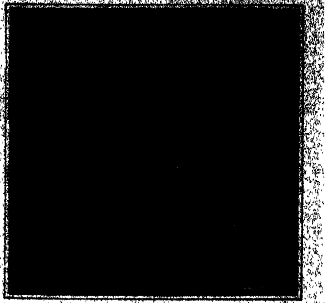
Two problems of special difficulty confront the designer of an automatic gun timed to fire a large number of shots at high speed, namely, keeping the barrel cool, and feeding the loaded cartridges and ejecting same when empty. By studying the accompanying illustrations, it will be seen that the barrel is inclosed in a close-fitting jacket, made of aluminium and formed with a number of radiating longitudinal fins. Fitting closely over the outside edges of these is a light steel casing 3⅝ inches in diameter. This extends beyond the forward end of the barrel. At each discharge the blast of gases from the muzzle acts as a kind of pump plunger and sucks currents of fresh air through the V-shaped channels surrounding the barrel. There is a passage of fresh cold air at each discharge, and this serves to cool the barrel without the use of water. Aluminium has six times the heat conductivity of steel, and the heat conveyed from the barrel to the aluminium fins is rapidly dissipated by the continuous passage of currents of air between them. The first few hundred rounds raises the temperature of the barrel to 330 deg. Fahr. Thereafter it rises more slowly, and after one thousand rounds have been fired it does not exceed 440 deg. Fahr. By varying the dimensions and form of the aluminium jacket, it is claimed that any desired limit of cooling may be secured.

Col. Lewis considers that the method employed for feeding the cartridges is an even more important improvement than the cooling device. In this design, the belts or long metal slips used in other guns of this character, are abolished, and in their place is a horizontal balanced rotary magazine, shown in part plan and in vertical section, in which the cartridges are placed radially, the magazine being attached upside down, over the breech opening, and held in place by a pivot stud on the receiver body. The operating spring is placed on the bottom of the gun, and is far enough removed from the barrel to avoid being affected by the heat of the barrel.

The energy required for loading, closing the breech, firing the cartridge and ejecting the empty case is obtained by diverting some of the gases of discharge through a small hole, drilled through the bottom of the barrel, a few inches from the muzzle. These gases act on a piston in a cylinder carried immediately beneath the barrel, the piston being at the front end of a long piston rod, the rear end of which is connected to the breech-operating mechanism. Col. Lewis describes the action as follows. When the gases act on the piston, the energy stored in the moving mass overcomes the resistance due to the work of unlocking the breech, extracting and ejecting the shell, turning the magazine to bring the next cartridge into place, and winding up the operating spring, which spring serves subsequently to close the breech and fire the shot. This complete series of operations may be completed at the rate of 800 times a minute; but the rapidity of fire can be regulated to a lower speed by adjusting the area of the hole through which the gases enter to act on the piston. The operating spring below the barrel at the breech is similar to that used in clocks, and it is mounted in a small oil- and dust-tight case in front of the trigger. The toothed periphery of the spring drum engages a toothed rack, formed on the underside of the piston operating rod. When the last is driven back by the gases, opening the breech and ejecting the spent cartridge, the spring is wound up by the action of the rack on the toothed periphery of the spring case. When the momentum of the rod has been expended in its backward travel, the spring comes into action, casting the rod back to its starting position, closing the breech and firing the charge. An additional advantage is that the friction set up by the gases impinging on the end of the tubular steel casing diminishes the force of the recoil one half. Hence, it is possible to fire the gun when holding it at arm's length—an advantage which makes it peculiarly fitted for use on aircraft. The weight of the gun is 26½ pounds.

The Canadian Arctic Expedition.—Press dispatches from Nome, Alaska, state that the "Karluk," the principal vessel of Stefánsson's arctic expedition, succeeded in getting out of the unseasonably heavy ice that now blockades the Arctic shore of Alaska, and making winter quarters. The other three vessels of the expedition, the "Alaska," "Mary Sachs," and "Belvedere," are fast in the ice, and therefore are not likely to reach their proposed base in Victoria Land this season.





Three stages in the interesting process of forging a ring, under the steam hammer, for a bevel ring gear.

Going Through the Shops—II

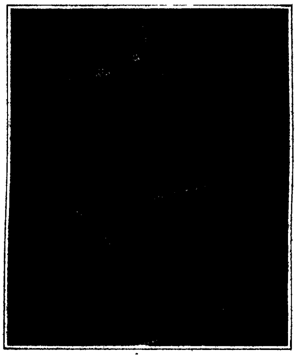
Our Associate Editor Sees How the Automobile Industry Has Stimulated Machine Tool Manufacture

By A. Russell Bond

FROM tinsmith to electrician, from wheelwright to upholsterer, a score of trades contribute to the manufacture of an automobile. It is almost too much to expect all these operations to be carried on in a single factory. The majority of motor car companies are content with the building of the motor and a few accessories, while some do not even do that, but purchase all the parts, including the motor, and in their own shop merely assemble them into complete automobiles. This is true even of high grade machines, for the parts, although manufactured outside are made according to the company's own blue-prints and specifications and under the eyes of their own inspectors. However, there are a few companies who make practically every part of the automobile in their own works, from the foundry and forge shop to the wheel and body building plant.

In this article we shall not attempt to describe the complete manufacture of automobiles, nor even single out any one branch of the work for detailed description, but we shall present merely a few scattered notes on interesting processes and machines that are to be found in the motor car factory.

A visitor, particularly a layman who does not appreciate all the technical details of the machine shop, is sure to find the forge shop most entrancing; for man has not outgrown his primeval fascination for fire, and a sight of incandescent metal still throws a mesmeric spell over him. It is wonderful to watch the ponderous hammer of the drop forge, dancing over the work and periodically coming down with a light tap that deftly shapes the glowing metal or with a resounding crash as it cuts away superfluous parts. The intricate shapes that are turned out by these power hammers are marvelous. The three photographs at the top of this page show some interesting stages in the forging of a ring for a large bevel gear. A rectangular block of white-hot steel is taken out of the furnace and hammered in the forge until it takes the shape of a bulging body with rounded shanks at each end. The body is then flattened and placed over a die at one side of the anvil, where at the next blow a slot is all but cut through the middle of the body, so that it looks somewhat like a chain link, as shown in the first photograph. At the opposite side of the anvil there is a depression flanked by a semi-circular boss on which the link is rested. A similar semi-circular boss on the hammer head is intended to enter the depression, so that when it descends it strikes the link with a shearing motion, spreading it open into a ring, as shown in the other two illustrations. Of course, the process is more difficult, consumes more time, and is more expensive than casting the ring, but the result is much toughter steel, and, considering the use to which the part is to be put, it is well worth the additional cost.



Mammoth press with which crowned fenders are formed.

Noisy as is the forge shop, it cannot compete in din and distracting confusion with the shop where sheet metal is hammered into various forms. Enormous steel presses cut out the fenders and body parts from sheet metal. One of our illustrations shows a large press stamping out a crowned fender. To this the side wings or aprons must be attached, and this is done by electric spot welding. Sheet aluminium is largely used in the building of the body. To bring this metal to the requisite contour it must be hammered. Some car

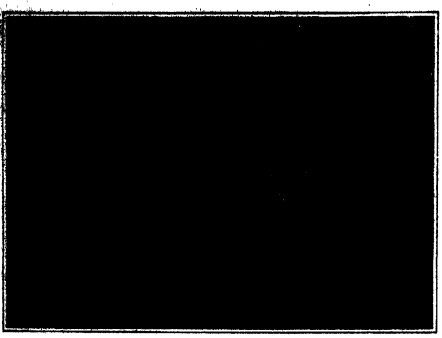
An enormous multiple drill operating on a frame side-bar.



Battery of multiple drills which operate successively on a cylinder casting.

bodies are made of cast aluminium, instead of sheet metal secured to a wooden framing, and curiously enough the cast bodies are actually lighter than the sheet metal bodies, for the reason that they do not have to have as much bracing.

In the body plant one views with interest the application of paint to the metal parts by dipping, and also by spraying with an air brush. The latter operates like the artist's air brush. A stream of compressed air injects a fine spray of paint which may be laid on very evenly. Automobile manufacture is a young industry, but it has grown to be one of the biggest in the country, and has furnished a great stimulus to machine tool manufacture. In fact, it has grown so fast that the tool maker has had a struggle to keep pace with it. It is constantly demanding special machinery, not only to save hand labor, but to save machine labor; that is, multiple and gang machines which will co-operate to perform the work that previously required the use of a number of machines. It has developed new methods in setting up the work on the machine. It has produced jigs of most ingenious types to save time in setting up the work and to insure uniformity of product.

In last week's issue of the SCIENTIFIC AMERICAN we told of labor-saving methods employed in the manufacture of the low-priced car. This may have led some to believe that in the higher priced cars labor saving methods are not employed. Because the higher priced cars are usually turned out in smaller quantities, it does not pay to carry the labor saving methods to the extreme requisite in the manufacture of the low-priced cars. However, where a great many parts are to be duplicated, where a single casting is to have a great many holes bored in it, where a great many operations are to be carried on at the same time on a single piece of work, and where the various operations require simultaneous operation in order to obtain accuracy and uniformity, special jigs and machines are employed. One of our illustrations shows the milling of a large number of spring hangers. These are mounted on the machines in batches of two dozen, and four milling cutters operate on them at a time, so that the opposite faces of each arm of the fork are finished simultaneously, and they must bear the proper relation, one to the other. Another illustration shows a multiple jig, the feature of which is the automatic device that holds the steel forged yokes in place, to prevent them from springing while the arms of the yoke are being drilled. Before this device was invented, great difficulty was experienced in drilling the holes in the arms of the yokes, and keeping them in perfect alignment for the reason that the upper arm, being unsupported, would be sure to bend under the pressure of the drill. In this jig a division plate is placed between the two arms, and the yokes are held in position against a stop by means of weighted levers. The weights on the levers are shown in the foreground. Six yokes are drilled at a time, and by the use of this special jig 2,500 yokes may be turned out per day.

Multiple-spindle drills are very largely used in many lines of manufacture, but seldom does one find a machine as large as the one here illustrated. It is employed in drilling the holes in the frame side-bars of a certain type of car The machine extends the full length of the side-bar and consists of a gang of six multiple-spindle drill-heads, all of which operate simultaneously on the work. Three of these enormous machines are required to drill the holes in a single side-bar. One puts the holes in the top of the bar, another in the side, and the third in the bottom. These three machines with six operators and a sub-foreman will do as much work in a day as twelve single machines with twelve operators, formerly. But not only is time and labor saved by the employment of this multiple machine, but the workmanship has been carried to a finer degree of accuracy. Another illustration shows a battery of multiple drills arranged in line along a track upon which run the jigs that carry the cylinder castings. The jig is moved from drill to drill, and rapidly centered under each, until all the holes in the castings are bored.

In last week's issue of the SCIENTIFIC AMERICAN we showed some horizontal milling machines operating on fifteen and thirty castings at a time. On this page we show a horizontal milling machine in which only four cylinders and crank cases are milled at a time. The machine is interesting however for the size of its milling cutters. The larger one is 22 inches and the smaller one 12 inches in diameter with inserted tooth cutters. After the work has been set up on the table it takes forty minutes for the revolving cutters to face off the opposite ends of the castings. Another milling machine, here shown, operates on six engine bases at a time, which pass between and beneath four large milling cutters, two of which are 15½ inches in diameter. In this machine the top and side of three engine bases are milled while the bottom and opposite sides of three more are being machined. The milling machine replaces four former machines and four operators. With two operators it can turn out 75 engine bases per day. However, the control of the machine

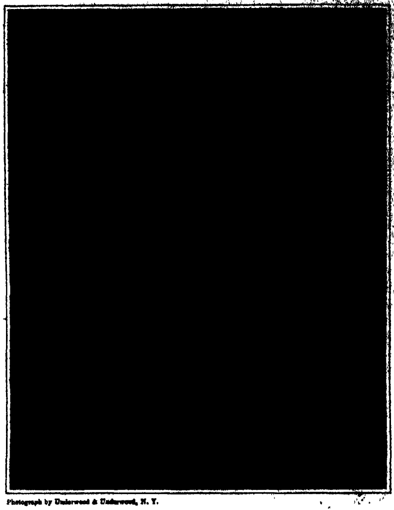
A New Mechanical Tunneling Machine

A Machine That Drills Into Rock, Loosens the Material and Removes It to Cars

FOR many years inventors have attempted to provide excavating machinery which would drill into the rock face of a heading, loosen the material and remove it to spoil cars at the rear of the machine for transport to some place of disposal outside. Many different forms of tunneling machines have been invented, but few, if any of them, have been able to stand up under hard work, largely on account of the effect of the rapid oscillation of their power drills and the constant jar and vibration of the entire machine. Furthermore, the continual renewal of the drills in all such machines has been an important and expensive item and has acted against their success.

In its issue of January 19th, 1909, the SCIENTIFIC AMERICAN described and illustrated a promising type of tunneling machine which powdered the rock by the direct impact of twenty-five piston drills mounted on a rotating head This machine had an extensive trial in service, but failed to meet the anticipations of its promoters. It was found that, like other tunneling machines, the fundamental principles of its design were faulty. The lack of success did not discourage the company which had developed the machine from further efforts in this field, and as a result of the efforts of Mr. Oliver O. App, the inventor, a new machine has been evolved on different lines which, for several months, has been under practical tests that are encouraging.

An experimental installation of this machine has been made at Marble Hill, 223rd Street and Broadway, New York city, where an open tunnel has been driven through the crystallized lime and quartz found at this point. With a full-sized machine, but with somewhat limited power, an effective demonstration of its working has been made, and a tunnel from 20 to 25 feet in length has been excavated through the extraordinarily hard rock there found.



Photograph by Underwood & Underwood, N. Y.

A tunnel borer that eats its way through rock, stone and sand.
Fifteen powerful rock-cutting pneumatic hammers strike over 1,000 blows each, with 25-pound hammers. A revolving disk carries the hammers.

The present machine consists of a rotary head carrying fifteen powerful pneumatic rock hammers which are directly in contact with the surface of the rock and revolve with the head. Instead of the piston type of rock drill used in the earlier machine, the new tunnel excavator employs drills of the hammer type chipping away the rock like the hammer and chisel of the stone cutter. The arrangement is such that the entire operation is automatically controlled and operated from the time of contact of the cutting tools against the face of the rock to the removal of the muck. It is here that the machine shows its superiority over other tunneling machines, for where the drills would operate whether there was any resistance or not, and in so doing would produce a very destructive vibration, in this machine the action takes place only when the cutting tool is directly against the rock, as the hammer does not strike the steel unless this condition is observed.

The construction of the machine will be seen from the illustration A revolving head carries the fifteen pneumatic drills, together with hydraulic jacks mounted at the upper part of two transverse diaphragms These jacks are secured into the roof and fix the position of the machine firmly in the excavation The head is moved against the surface of the rock to be excavated, and the drills, mounted on several holders, are individually and successively adjusted The machine itself is carried on wheels running on rails of standard gage, 4 feet 8½ inches, and its engine can be operated by compressed air, steam or electricity, air pressure being used in the present installation. As the main [illegible] revolves, the two screw jacks with a feed of [illegible] move the frame forward so that cutting tools [illegible] the rock and the speed of revolution of the head and the progress depend upon the nature of the material to be excavated. In soft material, such as shale, two revolutions per minute can be made, with progress of an inch per minute, or five feet an hour, while with very hard material, three, four or more minutes may be required for a single revolution. The center shaft carries the head and feeds forward the limiting distance of 3½ feet, after which the machine itself must be moved forward and set with the hydraulic jacks. Both the forward and rear diaphragms can be moved together or independently. The shaft itself is hollow, 12 inches in diameter with an 8-inch bore, from which compressed [illegible] rock is not cut but appears [illegible] as if it were lifted off in [illegible] concussion had [illegible]. In this way the common [illegible]ing to cut the rock is avoided, for it is realized that rock may cut steel quite as readily as steel will cut the rock. Consequently, when this excavating machine is put in adjustment the tools must be arranged so as to chip the rock. When the tools are in proper adjustment, each single tool must be set and locked.

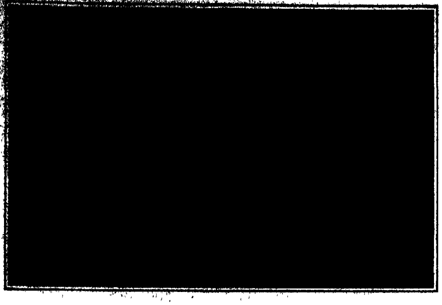
Photograph by Underwood & Underwood, N. Y.

The new tunneling machine.

The machine is so constructed that the cutting tools work only when they are against the [illegible] off automatically when its share of the work is done, allowing those with harder work to [illegible]. The action is similar to that of an auger boring through wood.

Researches at Kilauea

IN the November number of the *American Journal of Science* F. A. Perret publishes the seventh and last of a series of articles describing the remarkable investigations carried out at the crater of Kilauea, Hawaii, in the summer of 1911, through the co-operation of the Massachusetts Institute of Technology, the Carnegie Geophysical Laboratory, the Volcanic Research Society, and residents of Hawaii. A regular vulcanological observatory has since been established at Kilauea, and the investigations are still in progress. By means of a trolley, carried on a steel cable suspended over the crater, special thermometers were lowered into the liquid lava, which was found to have a temperature ranging from 1,050 deg. to 1,175 deg. Cent., though in virtue of its chemical activity the lava has the power of fusing metallic objects whose melting point is several hundred degrees above these temperatures. This paradoxical observation indicates that all estimates of the temperature of liquid lava based upon the melting therein of wires or strips of various metals are of practically no value. Samples of the molten lava were also collected by means of the trolley, and their subsequent examination led to some curious observations; e. g., that lava evolves much heat in solidifying, so that specimens maintained a stationary temperature for some three hours after being collected. A very important question, on account of its bearing upon the prevailing explanations of volcanic activity, is whether water of magmatic origin is found among the gases exhaled by active volcanoes. Its presence is denied by Dr. Albert Brun, who analyzed the lava specimens collected by Perret, but appears to be fully established by researches carried out in the summer of 1912, as reported by Drs. Day and Shepherd in the *Journal of the Washington Academy of Sciences* for November 4th, 1913. The later observers performed the brilliant exploit of descending into the crater and inserting a tube into the dome formed over a lava fountain, whence the gases were pumped into a number of collecting tubes. The latter were subsequently brought out of the crater, and the contained gases were analyzed. Considerable water was found to have condensed in all the tubes. Another notable discovery was that the nitrogen exhaled by the volcano contains no argon, and as the latter is always present in the atmosphere, it is concluded that the [illegible] does not contribute to the gases given off by the volcano. [illegible] water vapor, evidently originate entirely within the earth.



Twenty men seated about a table in an enormous locomotive firebox.

A [illegible]

THIS [illegible] shows [illegible]. This photograph was taken during the process of construction, and before the back head and flue sheet had been applied. There are twenty men seated about the table within the firebox. This is one of a lot of fireboxes now being built for the Philadelphia & Reading Railway, to be applied to their class I-8-A Consolidation locomotives. These locomotives are designed to burn anthracite coal, and hence the large grate area is requisite. These particular fireboxes will be built to form a combustion chamber between the bridge wall and the back flue sheet. The firebox consists of fifteen channel-shaped sections, each section being 20 inches wide over all. This firebox is 13 feet 2 inches long and 8 feet 8 inches wide inside dimensions. The distance from the bottom of the mud ring to the center of the crown on the inside is 5 feet 1 inch. It is expected that these fireboxes will be in service by next spring.

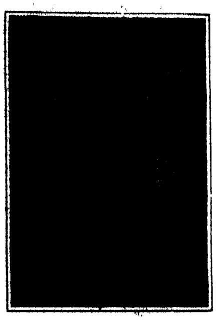
Brickwork Statuary

JUST as the Babylonians of old, on the Istar Gate of the Royal Castle, used to build up of glazed bricks their well-styled, imposing animal monuments, an attempt is being made to restore the brick to its ancient place of honor in modern statuary.

Instead of fixing a raw block in position and hewing it with the chisel, as is frequently done with the reliefs on English houses, thereby laying the brick open to atmospheric influences, and destroying the remarkably picturesque charm of the vivid colored material, the monument is molded bodily out of the unburnt brick clay, cut into layers and stones and each finished up carefully. In the kiln the molded parts are laid on a sand bed, insuring perfect mobility during the baking process and excluding any risk of breaking or bending. A perfectly uniform shrinking of 15 to 16 per cent may be accounted for. When the monument is next erected on the spot, the insertion of a proper thickness of lime-cement mortar into the joints between the brick layers restores it to the originally contemplated dimensions.

The accompanying photograph shows a figure intended for the monument of an African explorer to be erected in a German sea town. It is the joint work of a sculptor, Mr. Edzard of Paris, and Mr. Donandt.

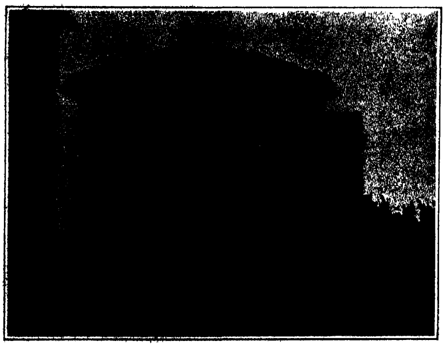
The monument, 33 feet high, grows out of a brickwork wall surrounding its base. The explorer, clad in his Moroccan burnouse, is shown astride on a camel, looking boldly out into the distance. This monument, rising above the river Weser, is to be a symbol of the spirit animating the seafaring population of the town which thus wished to commemorate the explorer.



A monument built of brick.

Up-to-date Corn Cribs

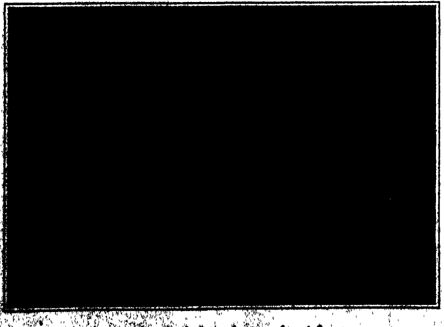
CORN cribs, like everything else, are liable to go out of date. The latest style is shown herewith. It is made of galvanized iron and concrete. It rests on the ground on a specially constructed circular concrete base which is guaranteed to make it absolutely mouse and rat proof and also weather-proof. It is an easy matter for the farmer to have his new style corn crib always full, for it is sectional like a sectional book-case, and therefore it may be enlarged or contracted to suit any crop. This one here illustrated was photographed at the Hamilton County Experimental Farm, near Mt. Healthy, Ohio, where several of them are in use.



Sectional corn crib that may be enlarged or contracted.

Clouds Formed Over a Forest Fire

IN the forest and brush fires which burned over many square miles in what is termed the "Back Country" north and east of San Diego this fall, an interesting phenomenon was observed on two occasions, when [illegible] were obtained by [illegible], of La Mesa, Cal., [illegible] as follows: "It occurred [illegible] on the 14th. The fire had been burning for several days despite the continuous efforts of hundreds of men working under the direction of the fire wardens, and had approached within from eight to twelve miles of La Mesa. Each time the phenomenon occurred on a clear, cloudless day. The first time as I watched the huge smoke columns filling the sky with their black pall, I noticed over one of the largest of the smoke columns a white cloud forming. It grew in size till it formed such a cloud as one frequently sees here hanging back over the mountains. A smaller one also began forming to the northwest of the larger one. The cloud was formed by condensation of the moisture driven up from the burning vegetation, and disappeared in a few moments. The phenomenon was repeated two days later, on the 16th, when a white cloud of peculiar beauty formed again over a heavy smoke column. It appeared like the snow-capped peak of some mountain; and resting as it did above the dense black smoke it presented a spectacle of striking picturesqueness, to which the accompanying picture does not do justice.



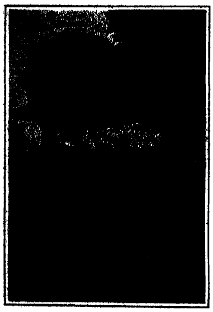
Cumulus clouds formed over a forest fire.

A Home-made Gasoline Tractor

IT occurred to a young Illinois farmer recently that he could make far better use of his three horse-power gasoline engine if he mounted it on wheels and converted it into a tractor. The photograph published herewith shows how the finished machine looked. The following is Mr. Everett Price's description of his machine and his method of constructing it· "By watching the 'Old Iron Man's' scrap pile different things were picked up and made use of. The hind wheels and axle are from a mower; the front wheels are gang plow wheels on an iron axle; the steering gear worm is from an old straw stacker and the hand wheel is a balance wheel to an ice-cream freezer. When running machinery using a tumbling rod, I use the jack shaft. Its ends are squared to fit an inch knuckle and it has a large belt pulley from a threshing machine keyed solid to it. It is run with a friction belt tightened by a lever and idler pulley. The pulley came from a corn planter reel, and the two levers from a gang plow. A second lever operates the traction gear. When lever is upright jack shaft runs free. When thrown forward engine moves forward, and when back engine backs. The bevel gears are from a mower and feed grinder. The pinions on the jack shaft are feathered. The large gear on axle is keyed solid, and axle is keyed solid to one wheel. It only drives from one side, but does not beat badly. The lever near the steering wheel operates the governor and sparker at same time. The speed ranging from 140 to 550 r.p.m. When I got the engine the speed was changed by a thumb-screw on top of the governor, and the sparker with a wrench, but by a few simple attachments both are changed together, giving a great range in speed.

"When traveling on the road, I travel about three miles an hour. I sit on a swinging spring seat, and have a foot-brake to use when going down hill.

"The tools I run are many and varied, such as band-saw, wood-turning lathe, disk sharpener, post drill, emery wheel stand carrying two wheels 2x12, sickle grinder, forge, two feed grinders, one for shelled and one for ear corn, two hole sheller and bucket elevators, sausage mill, pump, grain dump, cement mixer, wood-saw and anything else which can be run by belt or tumbling rod."



Home-made gasoline tractor.

Glass-Filling Drinking Fountain.—A drinking fountain has been patented, No. 1,072,124, to Charles Edmund Kells, Jr., of New Orleans, La., which shows a drinking fountain in which a shield surrounds the discharge orifice from which the stream of water issues and passes through the shield without coming into contact with it. When the shield is adjusted to an inclined position the discharged stream may be received directly by the mouth of the drinker or may be used for filling a drinking glass.

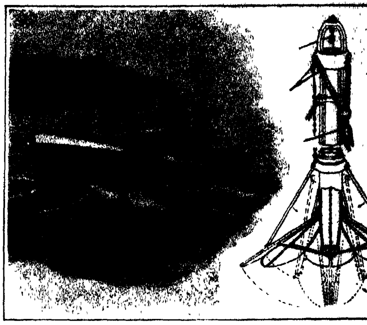
Device for Releasing Stranded Vessels

THE accompanying illustration shows a device which has been patented by Mr. A. E. Luzzi, the object of which is to assist the wreckers in releasing a vessel which has stranded on a shoal or on the beach. It consists of a pair of stout, steel columns, whose principle of action is similar, on a large scale, to that by which a boatman poles himself off the beach, or by which the old Mississippi steamboats were wont to pull themselves off or across a shoal of the river. It consists essentially of the two columns, a system of chains which are slung beneath the vessel, and tackles and gear by which, through the hoisting winches, part of the load of the ship is transferred to the columns, and the operation of backing off the shoal is thereby assisted. The foot of each column consists of a folding base, consisting of a number of segments hinged together and also hinged to the base of the column, all in such a way that they can be opened out to provide a broad footing in sand or loose material, or closed up, as shown in dotted lines in our detail sketch, in order to afford a stiffer base of less area when they foot upon rock. When the base is open, it is supported against the column by a set of heavy steel rods, which extends from the outside of the leaves to a common sliding ring, which brings up against a fixed ring firmly attached to the column. A chain is run from the inner face of each segment and is attached to a common sliding block at the base of the column, which is drawn up or lowered by means of a chain, leading through to the center of the column. The vertical movement of the block serves to draw the segments into the closed position as shown by dotted lines. At the top of the column, which is extensible to suit the depth of the water and height of the ship, is a chain sling, and from this a block and tackle leads to the mast and affords a means for maintaining the columns in the desired position with regard to the ship. Heavy chains are passed around the hull abreast of the columns, and by means of heavy tackle, and the hoisting winches on deck or other suitable means of power, a heavy strain is placed upon the columns and a part of the load of the ship transferred to them. To ease the strain on the lifting gear when the ship is rolling, heavy coil steel springs are interposed between the base of the mast and the gear. By this means it is possible to transfer to the columns as much of the load of the ship as the columns will bear, and this lightening of the ship, coupled with the backing of the engine and the strain on the hawsers of the wrecking tugs is depended upon to release the ship and float her into deep water.



Device to assist in releasing stranded vessels.

The Eskimos as Aboriginal Inventors

By A. L. Kroeber, Curator of Anthropology, University of California

WINDOWS without glass, the carpenter's brace, the first decked boat, a type of self-supporting vault unknown to civilized architecture, an artificial arm, are only a few of the achievements to the credit of the Eskimo; while he has solved the problem of drilling a curved hole, or sawing without a saw, with ease. Twenty-five thousand to-day, perhaps fifty thousand all told before the diseases of civilization and alcohol had begun to draw them from the height of their prosperity, the Eskimo population from Greenland to Alaska has always been less than that of a second-rate city among ourselves It is not amiss to say that they have produced more inventive geniuses, man for man, than any other people, not excluding the Anglo-Saxon race.

With the exception of but a few tribes, they live in a climate where wood and all products of the vegetable kingdom are unknown, except perhaps for such small quantities as the ocean currents may drift to their shores. One half the mineral substances, including the all-important metals, are also beyond their reach in the ever frozen north; even if they mined iron ore, they would not have the fuel to smelt it. Only products of animal origin—bone, skin, hair, and ivory—stone, and the elemental substances ice, snow, and water, are at their service.

The snow-house well illustrates this. The Romans and their predecessors worked out the true arch and vault, and the Mayas of Yucatan used the false arch, but the Eskimo builds a spiral vault, which needs no scaffolding. The details of this construction in snow have been previously described in the SCIENTIFIC AMERICAN of May 7th, 1910, so it need not be gone into again here; but one of the remarkable features is that when the house is completed, the builder is immured inside. This, however, is of little moment, for his bone or ivory knife slashes out in a few moments a door big enough to crawl through.

Next comes the window, which is cut out just above the door. How does the aborigine make this without glass? Nothing easier. He has saved up a seal bladder, or walrus intestine, and this, by the application of a little water, or when that is not at hand, saliva, is deftly frozen in a few instants into its frame.

This window is translucent, like our frosted panes; it admits light, but not vision. Something transparent is needed so that the inmates can see whether the clouds are clearing, or friends approaching. A slab of smooth ice, broken out of a leather bucket of water set outdoors for a minute, is therefore inserted in a hole cut in the gut.

Now Mr. Inuk, as he would call himself, is ready to move his family into their new quarters. But half a day of warmth from five or six human bodies, not to mention one or two cooking lamps, will begin to melt the snow walls from the inside. The inmates would soon be exposed to an ever increasing icy drip, until the roof disappeared over their heads. A system of portieres, or better, wall hangings, remedies this problem. Ten or a dozen old seal skins are hung by bone pegs just below the inside of the wall, leaving a narrow but clear air-space between the interior of the little cabin and its snowy exterior. The cold penetrates to this film from the outside; the slender heat inside does not penetrate beyond the skins; and all difficulties are avoided.

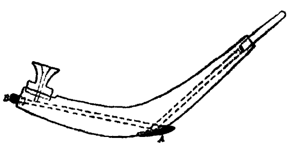
So, in a few hours, man, wife, children, and perhaps dependant old people, are comfortably installed; and that in a structure which not only can teach the engineer of civilization a lesson, but is provided by this so-called savage, and was provided by his ancestors, with wall paper and window at a time when our ancestors sat shivering in bare walls as far away as possible from the open windows they could not close without being in darkness.

But our Arctic genius is still far from the end of his troubles. Where the temperature is forty below zero, artificial heat is needed even indoors; and where meat is frozen so hard that it cannot be butchered, but must be chopped like wood, cooking is at least desirable, however strong one's teeth. Iron for furnace or range is not available; coal and wood not to be had; petroleum not yet discovered in the Arctic.

A stove is clearly out of the question. The apparatus must be a lamp. The material, it appears, must be stone. For fuel, seal oil, tried out from fat and blubber, can be used; and a wick can be made from dry moss. So the Eskimo shapes a triangular piece of rock, slightly hollows out the top, lays his wick along one side, pours on his oil, lights up—or rather his wife does so—and soon the pot is boiling and the pure snow melting into clean ice water for drinking. Such is the origin of the first oil cookstove invented.

But before meat can be cooked, game must be caught. In summer this offers no great difficulties, even in the Arctic. But in winter, when land animals are hibernating in hidden places, when fish lie torpid deep under the ice, when birds have flown thousands of miles to the south, and when the great pall of snow and ice covers the world, the Eskimo faces a difficult problem. If it were not for the air-breathing sea animals of the seal and walrus class he would starve in short order. But the seal cannot be hunted like other game. He has the intelligence of quadrupeds, and therefore net and hook and line will not catch him like fish. On the other hand, he lives in the water, and if wounded by arrow or lance would make good his escape, to die, perhaps, under the ice or out at sea, but out of the hunter's reach. Even if killed at the first shot, he would immediately sink, for strange to say, his body is heavier than water. The Eskimo therefore needs a peculiar weapon. It must be effective from a distance; and it must not only wound, but hold the animal. The need for such an implement has resulted in the invention of

(Concluded on page [illegible].)

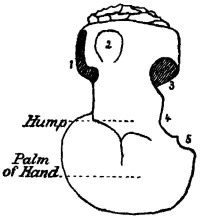


How the curved pipe is bored.

Note the detachable plugs *A* and *B*.

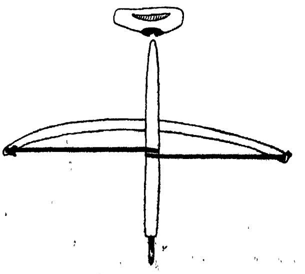
Left-handed spear thrower or artificial arm.

Finger depressions at 1, 2, 3, 4 and 5.



Woman's skin-scraper.

Thumb and finger positions indicated by numbers.



Carpenter's brace.

The mouthpiece has a stone socket-bearing and a groove for the teeth.

RECENTLY PATENTED INVENTIONS.

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the Scientific American.

Pertaining to Apparel.

SEAM FOR SEWED ARTICLES.—J. Bas[illegible], [illegible] Howard Ave., Brooklyn, N. Y. This invention relates to a form of felling for edge seams of coats and other garments. It devises a method for securing together layers of cloth forming the edge of the garment in a way to make the felling almost invisible, while providing an edge seam felling that can be worked by machinery from the inside of the edge and finished with the same neatness as if felled by hand.

BUTTON.—A. R. Commerford and Susan E. Watrous, 53 Ayrault St., Newport, R. I. This invention has reference to improvements in buttons such as are attached to garments, and has for an object the production of a strong reliable button of neat appearance which is formed of cord, tape, or other suitable material.

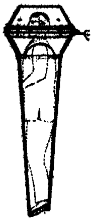
RING SETTING.—R. Rosenthal, 120 Chrystie St., New York, N. Y. The object here is to provide a structure for producing the same finish from the top of the setting downwardly through the ring. Also to provide an anchoring device and a deflecting device of the same kind as the fingers or prongs of the setting.

Pertaining to Aviation.

PARACHUTE.—A. Gokolak von Augeso, Baden near Vienna, Austria. This invention has for its object a mechanism for efficiently opening parachutes attached to persons or objects above the ground. Besides being a means of escape for aeronauts the device may be used as a fire escape in burning buildings, and serve for throwing up signal lights such as light balls, rockets or for firing projectiles from aeroplanes and balloons without subjecting the latter to recoil.

Of General Interest.

LIFE SAVING DEVICE.—E. E. Hills, Medina, Wis. The purpose here is to provide a container which will receive and hold a person upright in the water and protect such person from the water, floating wreckage and other conditions under which the usual form of life preservers would be unavailing. The container is of such a nature that the same with others may be conveniently stored on shipboard and readily and quickly placed in operation in case their use is required.



LIFE SAVING DEVICE.

FLOWER HOLDER.—W. S. Daniels, 872 Lexington Ave., New York, N. Y. This invention relates to flower holders for use in arranging and positioning flowers or the like in vases, bowls or other receptacles intended for their reception, and has reference more particularly to a device of this class which comprises a plurality of rods adapted to have the stems of flowers disposed among them to hold the flowers in place.

FLOWER HOLDER.

BUOYANCY TANK.—A. Erikson, Keith Estate, Babylon, N. Y. The tank comprises a hollow body having means for admitting air and water, and so designed that the pressure of the water upon the outside, no matter what the depth of submergence may be, is always balanced by the volume of air on the inside, so that it is impossible for the tank to be crushed under any conditions in raising sunken vessels and other submerged objects.

UMBRELLA.—J. W. Lewis, 134 Lower Terrace, San Francisco, Cal. This invention has for its object the provision of a simple and efficient means for detachably connecting the ribs and braces to the stick and runner respectively, wherein each connection is independent of the other connections.

SMELTING OR REFINING OF METALS AND THE LIKE IN CRUCIBLES.—H. G. Solomon, 4 Elgin Court, Elgin Ave., Maida Vale, London, England. This invention relates to induction furnaces applicable for crucible smelting and refining purposes. The object is to provide an improved form of induction furnace which shall be particularly, though not solely, applicable to the crucible process for making steel and steel alloys.

SECTION LINER.—B. Silverston, 22 E. 120th St., New York, N. Y. This improvement has reference more particularly to that class comprising a member having means to engage another member so as to form parallel lines in any desired direction and having any desired spacing between the said parallel lines.

Hardware and Tools.

RAZOR GUARD.—W. L. King, 32 N. 9th St., Indiana, Pa. This attachment guards the cutting edge of the razor against accidentally cutting the face of the user, and the clamp element and the guard are so arranged, that the latter will exert a pressure against the clamp to bind the same against the razor blade.

WRENCH.—O. P. Case, care of A. W. Davis, Canandaigua, N. Y. In this case the invention is particularly adapted for embodiment in monkey wrenches and relates especially to novel means for holding the movable jaw of the wrench in adjusted position relative to the fixed jaw.

Heating and Lighting.

SMOKE SEPARATOR.—C. F. Holmes, 37 River Front, Beaumont, Tex. This inventor provides a new and improved smoke separator designed for use in connection with smelter furnaces and other apparatus, and arranged to effectively prevent poisonous or obnoxious gases from passing into the atmosphere, at the same time retaining and saving valuable matter contained in the smoke.

SMOKE SEPARATOR.

SOLAR HEATING APPARATUS.—M. de la Garza, 408 S. Campbell St., El Paso, Tex. This invention provides an improved lens, and improved means for adjusting the frame carrying the lens, lens tube, and a casing to contain a heater or other apparatus. It is designed more particularly as an improvement on the apparatus forming the subject of U. S. Letters Patent, No. 696,326, formerly granted to Mr. de la Garza, although features of the present invention are not limited for use with the patented apparatus referred to.

FEED WATER HEATER AND PURIFIER.—T. O. Organ, 116 W. Seymour St., Philadelphia, Pa. The heater is provided with an oil separator having an inlet for impure steam and an outlet for purified steam, said outlet being located in the wall of the separator opposite the inlet, and provided with a flange projecting toward the inlet and an oil outlet forward of the steam outlet, a chest, the inlet of which is formed by the purified steam outlet of the separator. The chest has an outlet to the heater's interior, and a valve in the chest and controlling its outlet. The invention relates more particularly to the one disclosed in Letters Patent of the U. S., No. 781,453, formerly granted to Mr. Organ.

Household Utilities.

FLUSHING DEVICE.—N. J. Gondolf, 708 State St., New Orleans, La. This invention is intended for flushing tanks having a siphon, and a siphon starter that supplies a jet to the shorter leg of the siphon to start the action. It provides actuating devices for the valve means that command the water inlet, so arranged that the opening of the valve to start the siphon will be accomplished without submerging the ball float.

COLLAPSIBLE WARDROBE.—J. A. Hazzard and A. B. Jones, 1 Emily St., Cambridge, Mass. This dust-proof compartment can be suspended in any desired place, can be easily collapsed to a compact package of convenient size for transportation and the parts are so interconnected that none can get lost. The parts constituting the wardrobe may be quickly and securely assembled to form a dust-proof compartment.

BEDSTEAD KNOB.—S. J. Fletcher, Shepherd St., Ashfield, New South Wales, Australia. The object of the present invention is to effect certain improvements in bedstead knobs whereby the latter are supported more firmly, the provision of the screwed nut in the knob is obviated and the adjustment or removal of the knob may be more quickly effected.

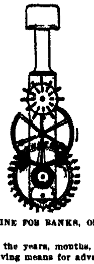
WINDOW WASHER.—G. D. Giovanni, 450 E. 151st St., New York, N. Y. This invention refers to improvements in window washers, and has for an object to provide an improved structure which may be adjusted in position and then operated until the window to which it is connected has been thoroughly cleaned.

Machines and Mechanical Devices.

FLASH MACHINE.—J. L. Courson, Barberton, Ohio. This inventor provides a construction which includes a number of receptacles receiving the materials for producing the flash, together with suitable mechanism for causing the materials in each receptacle to be ignited in turn in a positive manner when the camera shutter is thrown open to make the exposure for the picture that is to be photographed.

FABRIC FOLDING DEVICE.—H. S. Burnham, Lawtons, N. Y. This invention relates to fabric folding devices for use with sewing machines and the like, and has reference more particularly to a device of this class, which includes continuously movable means for rolling under the edge of a fabric to form a hem.

DATING MACHINE.—E. E. Gregory, Central City, Ky. Mr. Gregory's invention relates to dating machines, particularly for use in banks, real estate and loan offices, and more particularly to an apparatus embodying stamping wheels for the years, months, and days of the months, having means for advancing a pre determined number of days through a single actuation of a certain portion of the machine for this purpose.



DATING MACHINE FOR BANKS, OFFICES, ETC.

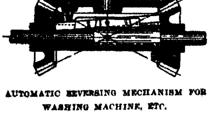
TRANSMISSION GEARING.—J. Chalmers, 60 Edison St., Quincy, Mass. The object in this instance is the provision of an improved structure in which power may be transmitted from one shaft to another through a plurality of gearing designed to change the ratio of rotation at the will of the operator

AUTOMATIC CHUCK—D W Wood, care of McNutt & Shattuck, 12 G A Knight Block, Brazil, Ind This invention relates particularly to a holder to be used on turret lathes, screw machines, or wherever an automatic chuck with a changeable collet is desired. By this invention the engagement of the hood with the spindle may be disalined or worn out without in any way affecting the alinement of the collet itself.

CAMERA.—A Voris, 15 Cottage St., Jersey City, N J. This invention relates particularly to devices having a reflecting mirror and a focusing plate, which will permit the operator to view a full-sized image The apparatus is foldable in compact casing when not in use, and may be unfolded or extended for taking a comparatively large negative

BOX MAKING MACHINE—G M Westland, 802-804 Main St, Winnipeg, Canada This invention provides a holder with means for indicating the proper place of the parts of the box and for holding such parts in place and so arranged that while the holder is firmly held in place on the support, yet it may be changed in position to bring the work into the successive various positions necessary for the different operations.

AUTOMATIC REVERSING MECHANISM.—T. H. Phillips, Jr., 38 Ridgewood Ave., Brooklyn, N. Y. The invention depends on the ratio of gears to cause automatic reversal of a driven shaft at any predetermined number of revolutions or with a fraction thereof. The mechanism can be used on washing machines, churns and topping machines. There are no cam wheels, dogs and ratchets, star wheels, sliding clutches or keyways or step by step operations to cause reversal.



AUTOMATIC REVERSING MECHANISM FOR WASHING MACHINE, ETC.

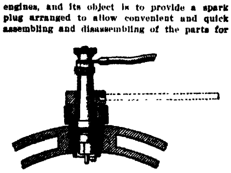
FIRE ESCAPE.—H. Croteau, 23 Villeneuve St., Montreal, Canada. This invention is so constructed that it requires but little power to operate the same, and is preferably in the form of an endless carrier moving over pulley wheels at the top and bottom, and being provided with rungs on which the persons escaping from the building can support themselves.

PACKING MACHINE.—J. Hochenauer, 2616 Grand Ave., Pueblo, Colo. This invention has reference to packing machines and more particularly to a double packing machine, the object being to provide simple attachments for actuating two packers in unison, doing away with all friction and other clutches and adapting the packers to run continuously.

FRICTION GEARING—C. N Whipple, 1019 Nora Ave., Spokane, Wash. The purpose here is to provide a device wherein means is provided for connecting a driving and a driven shaft by means of which the relative speed of the shafts may be varied without stopping or slowing either, and without any danger of breakage, stripping gears or the like.

Prime Movers and Their Accessories.

SPARK PLUG—J. J. Meyer, Yonkers, N Y. This invention relates to internal combustion engines, and its object is to provide a spark plug arranged to allow convenient and quick assembling and disassembling of the parts for removal of the electrodes for cleaning, repairing or other purposes, and to protect the assembled parts against injury by vibration or jars incident to the running of the engine.

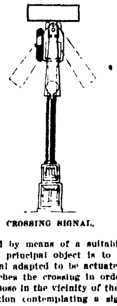


SPARK PLUG.

Railways and Their Accessories

CAR COUPLING—H R Swan, 938 Fifth Ave., Huntington, W. Va The object here is to provide an arrangement of structure whereby a gravity latch member may be utilized upon the tail of the knuckle and the parts moved toward and from the closed position without the destructive friction between the knuckle parts and the drawhead which is usually present in such arrangements to the detriment of all the parts

CROSSING SIGNAL—W. A. Hesse, Alameda, Cal This invention is particularly directed to mechanism adapted to be actuated by a train approaching the crossing, the control being effected by means of a suitable electric circuit The principal object is to provide a crossing signal adapted to be actuated when a train approaches the crossing in order to give warning to those in the vicinity of the crossing, the construction contemplating a signal characterized by an oscillating arm.



CROSSING SIGNAL.

Pertaining to Recreation.

AUTOMATIC FISH HOOK—F Forester, 124 Second St, Elizabeth, N J. This device has connected thereto pivotally a plurality of individual fish hooks and also has means whereby when one of said hooks is struck by a fish, a pull upon the line will cause the other of said hooks to become operative or to increase its catching tendency.

Note.—Copies of any of these patents will be furnished by the Scientific American for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

---

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States

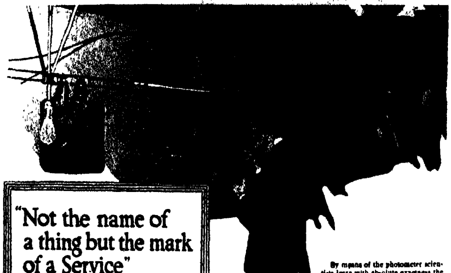
The meaning of MAZDA

Talks about MAZDA—No. 1



By means of the photometer scientists learn with absolute exactness the candle power of an experimental lamp, watching always for any indication of possible advance in lighting economy

"Not the name of a thing but the mark of a Service"

A SINGLE glimpse into that exceedingly busy place, the Research Laboratories of the General Electric Company, at Schenectady, would convince any spectator that science does not consider the great world problem of artificial lighting as having been finally solved. This headquarters of electric lamp science hums with an activity that not only tells the story of great things done, but that tells also the story of constant, vigilant, unremitting effort toward still higher achievement

But the fact about these laboratories that is of greatest significance to every user of electric light is the big plan and purpose behind these endless tests and experiments that are illuminating the path of further progress.

This big plan is expressed in the word Service. And the sign of this Service, the trade-mark of this maintained effort, this good will of a scientific movement, is "MAZDA"

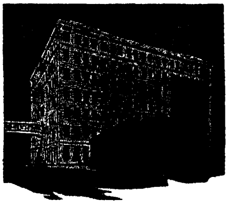
Every one of these tests, every laborious detail of these experiments—in glass, in filament wire, in "anchors," in chemical actions and reactions, in endurance, in economies of current, in practical use and facilities of manufacture—is telling the story of this Service, is giving to that Service trade-mark "MAZDA" the inspiration of a watchword.

The sustained brain-power of this Service—made visible day by day, month by month and year by year in the "MAZDA" lamp—has been creating lamp history. When the discovery of the availability of certain rare metals for lamp filaments, such as tantalum and tungsten, dethroned all earlier types of incandescent lamp, the new elements brought new mechanical and electrical problems The early tungsten filaments for example, while far excelling the filaments developed from other metals, were too fragile fully to meet the strain of the harsher uses to which lamps are subjected

It was in these Research Laboratories that these problems were worked out, and a method discovered by which the fragile tungsten paste filament was superseded by a strong drawn wire filament which not only gives *three times* as much light as the old style carbon lamps with the same amount of current, but is staunch enough to meet all the demands of modern usage. It is in these Research Laboratories that the step by step progress toward ideal light has attained other advances in construction, other increases in economy, by which the lamp of today that bears the mark "MAZDA" became possible.

To *carry forward* the work that has safeguarded the leadership of the "MAZDA" lamp, the distinguished corps of technical experts behind this Scientific Service is not only maintaining, without intermission, vast original investigation and experiment at this focal point of electrical science, but is keeping in touch with the great experimental laboratories of Europe.

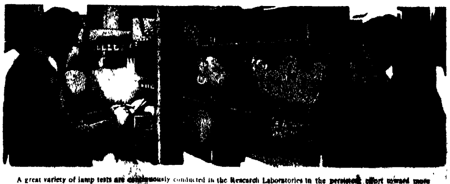
And "MAZDA" means more than the gathering of these products of scientific labor. The "MAZDA" Service plan means also that the laboratory experts at Schenectady keep equally in touch with the General Electric Company factories and the factories of other companies entitled to receive "MAZDA" Service, giving to each of these manufacturing centers every new fragment of knowledge which the skill of the Research Laboratories has selected as of practical application to the "MAZDA" lamp.



New building of the G-E Research Laboratories at Schenectady, headquarters for the scientific effort known as "MAZDA" Service. This service comprises constant experimentation and world-wide investigation, so that the mark "MAZDA" on an electric lamp shall always signify the latest achievement in metal filament lighting by the ablest lamp experts in the world.

Thus every lamp that bears the name "MAZDA" indicates that this Service has been applied to the production of that lamp. This is your assurance when you buy a "MAZDA" lamp—whether you buy it today, or tomorrow, or next month or at any future time—that you have the metal filament electric lamp that sums up the latest successes of the ablest lamp experts in the world.

GENERAL ELECTRIC COMPANY



A great variety of lamp tests are continuously conducted in the Research Laboratories in the persistent effort toward more and more efficient lighting, and demonstrated advances in this science are transmitted to the manufacturing centers entitled to receive this "MAZDA" Service.

4603

Protecting East St. Louis Against Floods

(Concluded from page 44.)

will work its way southward, filling the river between the new shore line and the levee for a distance of three miles.

The levee wall in front of East St. Louis is for a considerable distance about ten feet higher than the street level, while the Mississippi River at low stage is considerably lower than the street level. It would be an unnecessary waste of energy to drive the teams and trucks over the top of the levee wall and then down over the wharf to the boats, so the engineers constructed the levee to suit the conditions prevailing at the high and low stages of the river. When the river is at low stage the teams are allowed to pass directly from the street level on inclosed inclined planes running parallel to the levee wall through openings in the main levee wall. At the top of the inclosed inclined planes flood gates have been built. When the Mississippi River is high these flood gates are closed, and the teams pass over the levee wall by way of other inclined planes. This scheme enables the teams to reach the boats conveniently during high and low water.

Moving south we find the Cahokia Creek flood gates. These are operated on the same principle as the smaller gates we saw farther north. They hang vertically and the pressure of the water from the Cahokia Creek opens them. When the Mississippi River is high its pressure keeps them closed. South of Cahokia Creek the levee is the same as it is north of Madison.

Going Through the Shops

(Concluded from page 51.)

does not take all of their time, for they also run a grinding machine which grinds the top of each crank case where the cylinders fit on. A similar machine is used for milling both ends of the engine base at one set-up. Two special fixtures carry eight front supports and eight rear supports and enable one operator to turn out eighty pairs per day, whereas, formerly, four machines and four operators were required to do this work.

A special boring machine used for retouching and finishing the rear end of a crank case and engine pan is shown herewith. A double-ended star feed mechanism is mounted on rigid spindles. One set of cutters squares off the end of the crank case to the correct length, another set recesses it to proper depth to receive the forward end of the transmission piece, all of which is done automatically. Our last illustration shows a special boring machine operating on a flywheel. In the swivel turret head are two pairs of tools for machining the edge inner face of the wheel while still another tool operates on the outer face.

These fragmentary notes will give but a fleeting impression of the countless labor saving appliances and processes employed in a motor car factory. Lest one may gain the impression that labor is saved at the expense of accuracy we shall describe in the next installment the rigid tests which various parts, as well as the completed engine, must undergo in the high grade factory.

Aboriginal Inventors—the Eskimo

(Concluded from page 44.)

the harpoon, which the Eskimos have perfected beyond all other nations.

The harpoon is a lance with a long line attached. This rope, made of the skin of previously killed walruses, is, however, fastened not to the harpoon itself, but to its point. This point, or toggle-head, is detachable. While the missile is in flight, or penetrating the victim's body, the head is end on, presenting its sharp point. Once in the body of the seal, the head comes loose, turns broadside, and is prevented by this position, as well as its barbs, from being pulled out. The shaft, or harpoon itself, comes out, floats on the surface, or hangs free from the line. On the other end of this line, however, is Mr. Eskimo, holding on with a death-like grip. If he is hauling [illegible] for miles, [illegible] hauls it closer and [illegible] breathe, another harpoon [illegible] is plunged into it until it expires. And then not only he, but his family and their friends, have plenty for some days.

This sounds easy, but the Eskimo knows better. The seal has the keenest of scent and hearing, and is difficult to approach closely. On the other hand, the Eskimo's harpoon, if big enough to hold a large animal, is heavy, and can be thrown only a short distance. If the Eskimo were twice as big as he is, he could throw twice as far. If only his arm were double length, he could hurl double the distance. But he is a stumpy fellow, muscular indeed, but short limbed. Well, what does this surprising individual do but make himself an artificial arm, which lengthens his natural limb by fifty per cent!

The "spear-thrower" is what this apparatus has been called; but it is indeed an artificial limb. Even the most skeptical become convinced when they can see and feel the grips for each finger. A large groove in one edge exactly accommodates the thumb. In the other edge is a depression, or rather a series of three, into which the three last fingers of the hand fit neatly. The index finger has a hole all for itself on the under side, to give a good grip; this hole is just carried through, so that the nail of this finger coming from below almost meets the thumb.

The remainder of the implement is simple, consisting of a long, grooved extension, into which the butt of the harpoon fits, being held at the end by an ivory hook or peg. From this peg the spear is really propelled. As the "thrower" rises into the air with the arm, the spear is released by the clutching fingers, until, when the implement is vertical, the harpoon flies forward.

The increased effect of the "thrower" is also easily calculated. Assuming that it is sixteen inches long, it adds one half to the length of the arm. Now the arm forms the radius of a circle, or part circle, in which the extremity moves that propels the spear. If the radius is lengthened by half, this circle is increased by half. The spear covers this enlarged distance in the same time as it would if held in the unequipped hand; hence its velocity is half as great again. The velocity being higher, the distance traversed by the missile will be greater. Hence the implement adding fifty per cent to the length of the natural arm, adds also fifty per cent to the range of the Eskimo's harpoon, and more than doubles his chance of striking the game.

The same patience and ingenuity are displayed in carving out ivory handles for the stone-bladed knives which the Eskimo woman uses for scraping skins. Each finger, and even the palm of the hand, has its particular notch or exactly fitting depression, so that every part of the hand may obtain a firm grip and every ounce of effort be utilized.

With all the work she does, the Eskimo woman's hand remains small and delicate. Her scraper will only fit a lady's hand. A man, Eskimo or white, can no more properly grasp her tool than he could put his foot into Cinderella's slipper.

The scraper, as well as the spear-thrower, is of course carved individually to fit a particular person's hand. This enables one to tell at a glance whether the man or woman who owned it was right or left handed. Ninety-nine per cent of the implements for either sex are for right-handed people. Evidently right-handedness is not a product of effete civilization and school training, as we are apt to think, but goes back to savagery.

Though no tobacco grows in his land, the Eskimo dearly loves to smoke. Strange to say, while inhabiting a part of that continent which first gave tobacco to the world, the Eskimo uses a pipe of Asiatic type and origin, as shown by its small steep bowl and curved stem. How to bore a hole around the corner in this stem is no trick at all for our Eskimo. He drills from both ends and [illegible] holes at the middle of the stem, where [illegible] meet [illegible]. When the [illegible]

AGENTS WANTED

WANTED—One person each locality as agent for [illegible] Hiller Mop Co., 1385 Grand Ave., Chicago, U. S. A.

VACUUM CLEANER AGENTS. Absolutely new design in [illegible] powerful bellows vacuum cleaner [illegible] at $7.50. Write for particulars about [illegible] now. [illegible] Company, Box 909, Dayton, Ohio.

HELP WANTED

MINING and manuf. corporation needs young, ambitious [illegible], commercially able and technically educated, who can command $10,000 to help expand development. Can realize great profits from secured investment with liberal salary. A rare chance. Address, Box 483, Little Rock, Arkansas.

PATENTS FOR SALE

A PATENT on an improved lock and key for sale. Interested parties can obtain full particulars by addressing A. Sutter, One hundred and eighty [illegible] Ave., Union Hill, New Jersey.

PATENT FOR SALE. Sanitary back washing accessory. No competition on market. Good house to house canvas. For further particulars address [illegible], Box 485, Kalispell, Mont.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.
MUNN & Co., Inc.

Inquiry No. 9346. Wanted the name and address of parties manufacturing tobacco stripping machines, and other machines pertaining to cigar manufacturing and cigar banding machines.

Inquiry No. 9347. Wanted the name and address of an industrial school where dressmaking is taught in all its branches.

Inquiry No. 9348. Wanted the name and address of manufacturers having useful household necessities, with a view to obtaining exclusive territory for a house to house canvass.

Inquiry No. 9349. Wanted the names and addresses of the makers of machinery for making Malt Tonic, also a machine for making grease, and machines for applying plaster (Cement Gun).

Inquiry No. 9350. Wanted the name and address of the manufacturer of a printing press for the printing of [illegible]. The machine should preferably be worked by hand.

Inquiry No. 9351. Wanted to make some article out of wood which could be made from 1 inch [illegible], by party having 75,000 or more feet of waste per year which is now used for fuel.

Inquiry No. 9352. Wanted the name and address of a person who is in a position to get the state or county agency for articles of merit that can be sold to business houses or others at $5.00 or over. No kitchen utensils desired.

Inquiry No. 9353. Wanted the name and address of a manufacturer who can make flexible oil cans.

Inquiry No. 9354. Wanted the name and address of a manufacturer of a machine which will stitch silk around small metal rings.

Inquiry No. 9355. Wanted the name and address of the maker of triplex glass.

Inquiry No. 9356. Wanted the name and address of a manufacturer who can build an automobile wheel, also a cigar banding machine. Concerns in the middle West preferred.

DO YOU KNOW WHAT'S DOING IN YOUR OWN BUSINESS?

[illegible]

The Lectern(?) Patent Insurance Co. Ltd. is prepared to supply regularly to manufacturers, [illegible] or other interested parties, exclusive information concerning the latest patents and developments in any particular branch of commerce or industry, especially valuable to manufacturers outside the British Isles.

[illegible]

[illegible] sides of a mouthpiece, all the openings but one are neatly closed with [illegible] plugs, and a single airchannel extends from bowl to mouth-piece.

The drill with which this work is done is as ingenious as our best carpenter's braces, though simpler in construction. The bit is a stick with a hard sharp-pointed stone set in the end. It is turned by a string looped around it. The ends of the string are knotted to a curved ivory bow. When the workman fiddles this back and forth, the string of course moves with it, and the drill is twirled. To hold it up and steady, a snug socket is set on the top; and the oval piece that contains the socket is shaped to fit—the mouth. Thus the workman grasps it with his teeth, leaving one hand free for the operation of the bow, and the other for holding or manipulating his material. So in this device there is truly the origin of the carpenter's brace, just as Eskimo tools and appliances always evince the height of aboriginal inventive power.

Smut Diseases and the Threshing Machine

THAT the threshing machine is one of the principal means of spreading smut diseases in grain is emphasized in a recent article by H. T. Güssow, Dominion botanist of Canada. A machine that has been used for threshing smutted grain is so fully infested with spores that any grain subsequently threshed, unless the machine is properly sterilized after use, will become liable to infection. Moreover, in traveling from one farm to another the infested machine scatters spores along its route. Dr. Güssow urges the enactment of legislation against this evil analogous to that already in force in some provinces of Canada against the spreading of weed seeds by threshing machines. The laws requiring that the machines be swept free from seeds after use should also require thorough disinfection, which may be readily carried out by inclosing bags or sacking soaked in formalin solution in the machine for a few hours, and spraying the exterior parts and implements with the same solution.

Maize Sugar

MR. O. W. BARRETT, the versatile horticulturist of the Philippine Bureau of Agriculture, takes a hopeful view of the possibility of maize becoming a serious rival of cane in the sugar market, and advises Philippine planters to experiment along this line, notwithstanding the unsatisfactory results of experiments already conducted in the United States. The maize plant, when deprived of the ears at the time starch is being deposited in the kernels, i. e., when the seed is "in the milk," develops a remarkable saccharose, or rather glucose content. Thus, the agricultural chemist of the Rhodesian government finds as high as 12½ to 14 per cent of sugar and about 1 per cent of glucose in the decobbed maize stalks in his experiments, which is above the average yield from sugar cane. Mr. Barrett quotes the opinion of experts that maize "will be, through its wonderful variability under the hybridizer's hands and its adaptation to man's varied needs, the greatest crop of the future."

How to Make a Measurer of Liquids

A VERY simple method for making a container for liquids which measures off say a quart at each time the liquid is poured, is to take a large cylindical can and put in a false bottom which holds about a quart between this and the bottom of the vessel. At one side of the false bottom is an opening which connects with the main body of the can, and on the other a tube leading to the mouth of the vessel, so that the mouth connects in reality only with the before mentioned space. This space being filled with the liquid, we tilt the can down so as to keep the level in the main chamber below the orifice and prevent further entry to bottom chamber, so that the bottom chamber now holds just one quart and can be emptied at the mouth of the can.

—"And you must take Sanatogen regularly for several weeks"

THIS urgent advice is given by physicians day by day in every civilized land—wherever sufferers from starved nerves and poor digestion seek relief. There is a reason for this. Physicians know that Sanatogen is a substance capable of supplying the real needs of a starved, overwrought nervous system—that it is a scientific combination of albumen and organic phosphorous—a compound eagerly absorbed by the hungry tissues and possessing unique tonic and reconstructive qualities. They also know from their *own observation* what Sanatogen has done for others. They have watched its revivifying action on persons whose nervous strength had been undermined by overwork, worry or disease; they have observed how it has infused renewed energy, life and elasticity into starved nerves; how it has regenerated the appetite, digestion; in short, how wonderfully it has helped to make the human machinery fit to perform its functions in the most perfect manner.

There are on file with the owners of Sanatogen no less than 18,000 letters from practicing physicians praising, endorsing Sanatogen. Truly, a magnificent monument to the value of this food-tonic.

But no less impressive is the enthusiastic testimony of patients themselves. Men and women in the forefront of human endeavor, statesmen, prelates, authors, lawyers, have written above their own signatures of the wonderful benefits received from Sanatogen.

A NEW BOOK BY ELBERT HUBBARD—FREE
A new book, "Health in the Making," by Elbert Hubbard, in his attractive manner and style, filled with his shrewd philosophy, together with capital advice on Sanatogen, health and contentment, will be sent free for the asking.

Sanatogen is sold by good druggists everywhere, in 3 sizes from $1.00

THE BAUER CHEMICAL COMPANY
28G Irving Place, New York

Sanatogen received the Grand Prize at the International Congress of Medicine, London, 1913

Prof. Thomas B. Stillman, M.S., Ph.D., the well known research chemist of New York, writes:

"The chemical union of the constituents of Sanatogen is a true one, representative of the highest skill in the formation of a product containing phosphorus in the organic phosphate condition, and so combined that digestion and assimilation of Sanatogen are rendered complete with the greatest ease."

Col. Henry Watterson, the famous Editor, writes:

"I feel I owe it to truth to state that I have made a thorough trial of Sanatogen, and that I have found it most efficacious and beneficent. I do not think I could have recovered my vitality, as I have done, without this Sanatogen operating equally upon the digestive organs and nerve centers."

Prof. C. A. Ewald, of Berlin University, Doctor honoris causa University of Maryland, states in his contribution on "Typhus abdominalis":

"I can say that I have used Sanatogen in a great number of cases (that is, in those disturbances of metabolism which were mainly of a nervous or neurasthenic origin) and have obtained excellent results."

Charles D. Sigsbee, Rear Admiral, U. S. Navy writes:

"After a thorough trial of Sanatogen, I am convinced of its merits as a food and tonic. Its beneficial effects are beyond doubt."

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12899) O. O. B. G. asks: 1. What force is it that causes a pendulum to swing up after it has fallen through an arc? The point of dispute is, one maintains that it is momentum, and the other says that it is inertia. Of course, the relation of the two is very close. A. Momentum is the force which carries a pendulum along its swing. Inertia is not a force. It is a property of matter. It expresses the inability of matter to move or stop itself. That is all there is to inertia, simple inability. Momentum is a force. It is measured by the product of weight by velocity. 2. Why is steel used to make springs instead of copper, or preferably to that metal? One party maintains that it is because the elasticity of the steel is greater, and the other maintains that it is because the tenacity of steel is greater. Also he (the latter) asks why, if the first is correct, that rubber is not used preferably to either of the others because it is most elastic of all substances. A. Steel is used for springs because it is both elastic and strong. Copper has very little elasticity, and little strength, or tenacity. Rubber is used for such springs as it is adapted to. It has a wide range of elasticity, and will stretch much farther than steel, but its elasticity is soon lost. Its elasticity of compression and stretching is valuable, but not its elasticity of bending. The elasticity of bending in steel is most valuable. Rubber is not the most perfectly elastic of all substances. Steel and glass are more perfectly elastic than rubber. Both retain their elasticity for many years, even indefinitely.

(12900) H. M. S. asks: Can you give me a formula for making bright red prints from photographic negatives by the ferro-prussiate process? A. A process for making red prints from prussiate paper is given in our "Cyclopedia of Formulas," page 701, price $5. "Float the paper 4 minutes on a bath of nitrate of uranium (not strong) drain, and dry. Expose under a negative for 8 to 10 minutes. Wash, and immerse in a bath of ferricyanide of potash, 30 grammes, water 3 ounces. When the print is red it is fixed in running water." You will find many processes for different tones in this valuable cyclopedia.

(12901) R. O. U. asks: Can you give me any information as to whether at any time there has been manufactured and sold a ball nozzle on which the ball was loosely laid in the cup of an ordinary nozzle, so that it would fall out if the nozzle were not held almost exactly upright, but when the water was turned on, it threw a very fine film of water without throwing the ball away? This seems to me a preposterous statement as I make it, yet several friends have vouched for it, claiming to have seen it in action, although the only ones that we could find in the hardware stores or at home had the ball O. K. but had a wire loop to keep it in position. A. The ball nozzle acts just as you describe it, although it seems strange at first thought that it should do so. The wire loop which is put across the mouth of the nozzle to hold the ball, is to hold it in place when the water is not turned on. As soon as the pressure of the water comes, the ball is forced in hard against the water and cannot fly away. The pressure of the air holds it against the water, and the water is spread in a spray over a very wide space. The explanation is very simple. You will find it in Hopkins, "Experimental Science," vol. 1, page 90, as the Ball Experiment. The ball forces the water to spread out as it issues from the nozzle, and thus the pressure is reduced below that of the air, and the air presses the ball into the cup of the nozzle.

(12902) A. Y. B. asks: Can a vessel be made of any other matter outside of glass that can retain a vacuum permanently? A. Any vessel of metal which is strong enough to withstand a pressure of 15 pounds per square inch may be used for vacuum purposes. It will hold a vacuum indefinitely, if the valves are made airtight at that pressure. The carbon dioxide cylinders and the oxygen and gas cylinders for the calcium light hold several hundred pounds of pressure for many months with very little leakage. They are of steel.

(12903) T. G. asks: Wishing to magnetise (permanently) a steel bar about 10 inches in length, I have wound nearly its entire length with twelve layers of No. 12, insulated, copper wire. There is a dynamo here, with a direct, maximum current of 2,500 volts. Now will you kindly favor me with a reply to the following: 1. Will it be sufficient to connect the ends of the coil, each with one of the poles of the dynamo? A. It will not be enough to connect your coil with one pole of a dynamo. No current can flow through a wire unless both ends of it are connected to the circuit, at points which are at a different potential or voltage. 2. Will a current of 2,500 volts be too strong for No. 12 wire, and should, therefore, a current of lower voltage be used? A. It will not be safe to connect your wire to the two poles of a 2,500 volt machine. The wire would be melted in a few seconds. 3. The manager of our local electric light plant says that on the loose ends of the wire, between the connection with the poles of the dynamo and the coil, one or more electric light bulbs must be affixed. Is that really necessary? A. You should have as many lamps less one as there would be placed in series for ordinary lighting. Let the coil be put in where one lamp would be put, and it will probably not overheat, and the current will magnetise the steel bar. 4. I have read that the magnetic or electric current does not affect the entire body of a wire or a bar of steel, but affects the metal only upon the surface and to a small depth below the surface. If this is true, will not a steel tube, with an inner diameter of 1 inch and a wall of 1-8 inch, containing three separate inner tubes (concentric), each also with a 1-8 inch wall, and each of the tubes magnetised separately, have far more magnetic (i. e. attractive) power than a solid steel bar of 1¼ inch diameter and of the same length. A. A magnet made of a number of thin pieces of steel is usually stronger than one made of a thick bar of the same weight. Probably steel tubes can be magnetised and fitted together so as to make a stronger magnet than a solid bar of the same weight.

(12904) C. E. O. asks: I write to you for information concerning the year 1900. Was it a leap year? And if not, please send me a Scientific American Supplement explaining why it was not. Some say it was, and some say not. Please send also a list of all your Scientific American Supplements and Catalog of Scientific Works. A. The year 1900 was not a leap year, neither was 1800, nor 1700, but 1600 was, and 2000 will be a leap year. The ordinary year is 365 days 5 hours 48 minutes and nearly 46 seconds long. If one day is inserted every 4 years, which is 6 hours a year, this is too much by 11 minutes and 14 seconds, and by dropping the extra day three times in 400 years the calendar will be kept very nearly with the sun for many centuries. This was discovered by Pope Gregory XIII, and this calendar is for that reason called the Gregorian calendar. Pope Gregory XIII died in 1585, so that his calendar has been in use in Catholic countries since the beginning of the 17th century. In England it was not adopted till 1752, at which time the beginning of the year was shifted from March 25th to January 1st. Thus our present calendar has been in use but 161 years. You will find this in Todd's "New Astronomy," which we send for $1.45 postpaid.

(12905) G. A. C. asks: Can you tell me if there are firms which by some method make nitric acid from the air? A. Large quantities of nitric acid and nitrates are now made from the air by the agency of electricity. The principal plants are in Norway, where water power is cheap. We have frequently described them and reported their progress in our columns. We refer you especially to Supplement 1640, 1641, 1642, 1643, 1644, 1667, 1668, 1691, 1692, 1746, 1748, 1784. These twelve numbers we will send you for ten cents each, and they will give you a wide view of what is being accomplished in this direction. Probably more than 100,000 tons of commercial fertilisers and reagents will be made this year by this process.

(12906) E. H. asks: Will you please tell me the deepest distance that a man has ever dived in a diving suit or other deep sea equipment? A. A man with a metal suit is said to have gone down 300 feet under the surface of the ocean. Men however do not work below 100 to 125 feet for any length of time.

(12907) C. A. B. asks: What influence has the moon, if any, on the weather? We think that an expression of opinion coming from so eminent a source as the Scientific American would be of great interest to a large number of your readers. A. The moon has no influence upon the weather, so far as the Weather Bureau has been able to detect, after a long time spent in studying the changes of the weather and the course of the moon. There is always a storm in progress somewhere around the world, and if a full moon occurs it is evident that it will be stormy where the storm or low barometer is at that time and fair where the high barometer is, while the change of the moon occurs at the same time to all parts of the country. Storms have no connection with the phases of the moon.

(12908) G. A. B. asks: Please to tell me through your paper how the temperature of the ocean varies with its depth in the torrid zone. At what depth does it reach the freezing point? A. The temperature of the ocean water does not reach the freezing point anywhere in the torrid zone. If it did, it would freeze and not be water, but ice. The lowest possible temperature below the surface of water everywhere is that of the maximum density. In fresh water this is at 39 deg. Fahr., and for salt water it is somewhat lower, but not much lower.

(12909) J. S. P. asks: Will you please explain the cause of the following mysterious experience? The writer with others, ladies and gentlemen, spoke in rotation into a recording phonograph. In the reproduction all the voices came out clearly except where the writer's should have been, but there the record was silent, not a sound. His voice perhaps was the heaviest of the company. The aim was to maintain the rate of revolution of the machine the same throughout. A. We have often noticed in testing voices that what seemed to the ear to be the stronger voice did not affect the recording stylus of the phonograph as much as a voice which seemed much lighter. We have attributed it to the fact that a heavy voice, that is, one of a low, deep tone, is frequently destitute of the upper partials which give fullness to the tone, and, we think, affect the recording apparatus more strongly than do the lower tones.

Makes Talking Machines Sound Life Like

This is the Original and Genuine Morse Clarifier

A remarkable little device made to fit in tube adjoining reproducer of any make of machine. It renders the sound *loud, clear, lifelike* and eliminates that unpleasant metallic effect. Easily inserted without marring or adjusting machine and everlasting.

$1.00 Mailed Prepaid. Send dollar bill, stamps or check at our risk. GUARANTEED *absolutely satisfactory or money refunded.* References, any bank in Minneapolis. In ordering state whether for Victor, Victor Victrola, Edison Cylinder with metal or rubber connection, Edison Disc, Columbia Disc, with new bayonet or former tone arm or Columbia Cylinder. Information matter free. Buy our extra fine imported needles, medium and loud, 5 cents per hundred postpaid.

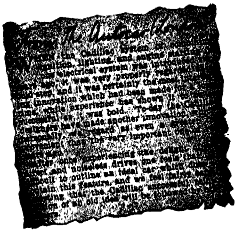
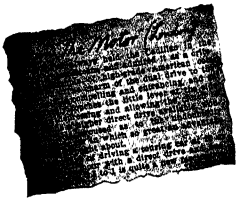
Cadillac
Standard of the World

The Cadillac two-speed direct drive axle is accepted as the most progressive motor car development of the year

Press comment abroad and at home makes that perfectly clear

It presages the trend of motor car engineering





It is the all-absorbing topic in American and European trade and engineering circles, and the second award of the Dewar Trophy to the Cadillac has accentuated the intense interest.

And these native and foreign engineers and editors are merely saying in technical terms what the first Cadillac owner you meet will tell you in much simpler language.

The owner of a new Cadillac—and more than 7500 of the new cars are now in operation—will tell you in blunt, plain English, that he has never ridden in a car which compared with it.

He may not argue the merits of the two-speed direct drive principle.

He will simply say:

"Get in and ride with me and you will agree that you never experienced a sensation so much like floating through space."

And if you do ride you will agree with him.

There have always been Cadillac owners, thousands of them, who would not concede for a moment that more money could buy a better car.

But there are thousands who go much further now.

They will not admit that any car is comparable in its riding qualities to this new Cadillac.

And there are other things as well which they will not admit.

Above all, they will not admit that there is a car which is comparable in those dominant characteristics which earned for the Cadillac the second award of the honor most sought by European makers—the Dewar Trophy.

That award stamped the Cadillac as possessing in the highest degree, those qualities which make most for all around practicability, for day-in-and-day-out and year-in-and-year-out constancy, satisfaction and service in the hands of the every-day user.

Dredging Out the Culebra Slide

In bygone ages that strip of land ten miles wide by forty long, which is now known as the Canal Zone, was under water. Its upper layers or strata were formed by a slow deposit of solid materials, which, in the course of ages, settled to the bottom and became more or less compacted. Ultimately, volcanic action raised this portion of the floor of the ocean above the level of the sea and formed the Isthmus of Panama. The bed of the ocean as thus elevated was lifted irregularly and in considerable confusion. Here and there, the molten igneous rock was forced up through the overlying marine deposit, destroying the general level and producing that confused topographical appearance with which every visitor to the Isthmus is familiar. When these volcanic agencies quieted down many centuries ago, the dry land, as thus formed, consisted of ridges of hard igneous rock, between which, broken up into great confusion, lay the above mentioned masses of submarine deposits, in various stages of hardness, but possessing very little resistance to crushing or sliding or other movements, should the conditions of equilibrium into which it had settled be once disturbed.

Then came the engineer with his drilling machines, dynamite, steam shovels and dredges, and proceeded to cut a deep and broad pathway through this geologically confused mass of material. Where he encountered the volcanic rock, that material stood up to the arbitrary slope which the engineer had determined upon for the sides of his great excavation; but when he cut into the looser marine deposited material, he began to get into trouble. Nature took the matter in hand, laughed at the engineer's contours and slope stakes, and proceeded to grade the sides of the cuttings according to her own liking. Generally speaking, she preferred a slope of one to seven, as against the engineer's slope of one to two. As a matter of fact, nature has been a very active agent in the excavation of the Panama Canal; for between thirty and forty million cubic yards must be credited to her activity as against one hundred and ninety million cubic yards done by the engineers of Uncle Sam, or, say, something over one sixth of the whole.

Very early in the work did nature begin to have her say in the matter of digging a canal at Panama. In fact, over thirty years ago, when the French commenced excavation at the deepest point of the canal, the Cucuracha slide caused the French engineers many an hour of anxious thought, and as the Cucuracha slide was the first, so to-day it is the last problem to be solved.

The accompanying illustration shows the dredges at work on this slide. The deepest excavation at Culebra occurred where one of those great masses of igneous rock forced their way through to the surface. Immedieeately to the south of it, and on the east side of the canal, is a large pocket of soft material which, with rare intervals of repose, has been steadily slipping down into the canal prism, as the work of excavation went down and the toe of the slope was cut away. So long as the steam shovels were at work, it was possible to shovel the material out about as fast as it came. When the tracks were taken up and the shovels removed, previous to blowing up the Gamboa dike, there was an interval in which the slide had, perforce, to be left to its own devices, and it moved into the cut until the prism was filled up approximately to the full depth of 45 feet.

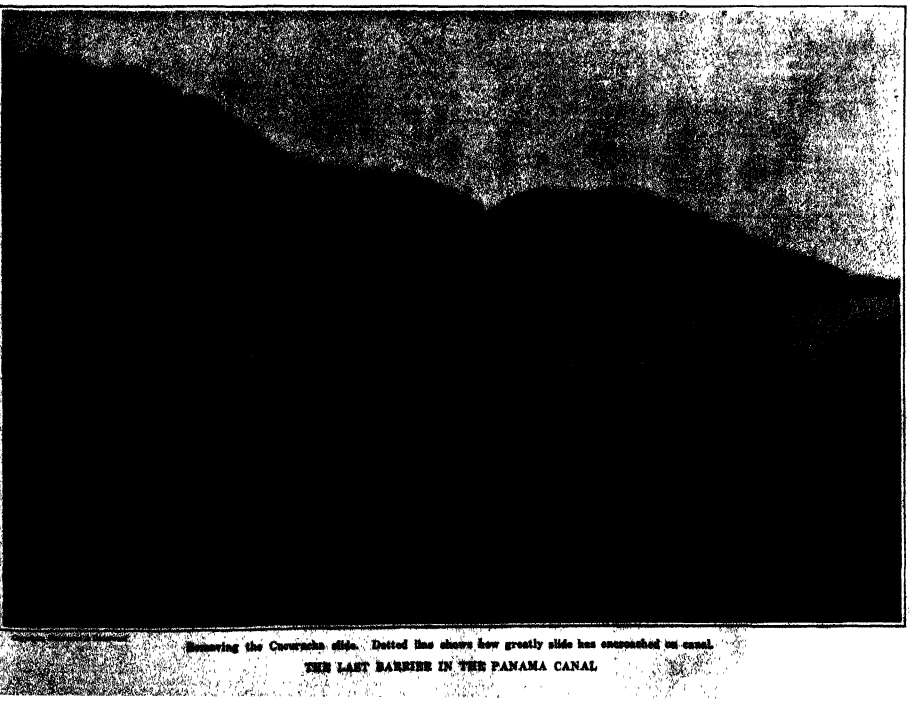
For several weeks past a whole fleet of dredges has been attacking the slide, and, according to the last dispatches, the channel through the base of it has been widened to a width of about 150 feet and a depth of 16 feet. The dotted line in our illustration shows approximately where the eastern bank of the canal should be. All the material on that side to the west of this will have to be taken out. The excavating plant, according to the latest dispatches, consists of three dipper dredges and two ladder dredges. Two 15-yard dredges, now nearing completion, will soon be at work, and they will make short work of the slide—probably.

A New Source of Paper Pulp

THE alarming dearth of raw material for paper making has stimulated research in this direction for several years. *La Revue* gives an account of the successful efforts now being made to produce excellent paper pulp from the *Hedychium coronarium*, a fibrous plant of the ginger family, having its origin in India, but growing in tropical parts of Asia, Africa, and America. The members of this family have fibrous stalks of various heights ranging up to 2 feet 6 inches or more, and covered with leaves

From the dry fiber a very good pulp is obtained, one hectare of land yielding 14 tons of fiber, which produces about 8 tons of pulp The cultivation demanded is inexpensive, and there are two or three harvests a year.

The process of treatment is simple—the plant is cut, pressed between rollers to dry it, beaten, and then heated with a varying proportion of soda. It may be *broken* instead of beaten, but in this case the paper is less fine in quality, though on the other hand it is much tougher.



Removing the Cucuracha slide. Dotted line shows how greatly slide has encroached on canal.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Ships that Break in Two

OCCASIONALLY, but fortunately very, very rarely, ships have been known to break in two while they were being driven across the seas. Several years ago this thing happened to the fastest torpedo-boat destroyer in the world, the "Viper," which was credited with having made thirty-six knots over the mile course. It happened last week to a large tank steamer before it had traveled very many miles from Sandy Hook.

The breaking of a ship's back is a common occurrence in cases where they have run upon the beach, or fetched up on a shoal of sand or rock—but that is to be expected. In these cases the breaking apart generally results from a falling tide leaving the vessel supported only amidship or only at the ends. As the tide falls away from the vessel, and her weight becomes less and less water-borne, the longitudinal bending stresses increase, till a point is reached where the plating tears apart, generally along a zigzag line of plate riveting or along a vertical straight line of bulkhead connection.

But it is not necessary that a ship be on the beach, or hung upon a shoal, to run the risk of having her back broken. This catastrophe, as the disasters to the destroyer "Viper" and the tank-ship "Oklahoma" show, may happen on the high seas and in deep water. It occurs very rarely, largely for the reason that several contributory conditions must be present simultaneously before it will happen. In saying this, it will be understood, of course, that poor design may wreck any ship that sails the seas. If the naval architect fails to build his ship with sufficient depth in proportion to her length, or if she be shallow and he fails to put sufficient extra metal into her bottom and upper decks to give the proper girder strength, she is liable to break in two in her first encounter with heavy weather.

But we are not considering poorly-planned vessels. The destroyer "Viper" was designed by a prominent architect, and built in one of the leading yards of Great Britain; and the tank steamer "Oklahoma" was constructed in what is considered to be the finest shipbuilding yard in this country, and presumably she was well designed.

Just here, it may be well to state that the bending stresses tending to wreck a ship so far as wave action is concerned, come either when the ends of the ship are deeply immersed in two following waves, or when the body of the ship is deeply immersed, and the two ends are in the troughs of the sea. Under the first condition, the ship may be considered as, roughly speaking, a bridge supported on two end piers. Under the second condition, it may be considered as a drawbridge swung open and supported at its center. In the first case, the ship will tend to sag amidships, in the second, to sag at the ends

Now these conditions will be aggravated when the distance from crest to crest of wave is approximately the same as the overall length of the ship, particularly if the seas are short or steep The stresses tending to bend or break the ship can also be very seriously affected by the loading Thus, a ship that is running light as to cargo, and is water-ballasted forward to offset the weight of engine and boiler and full coal bunkers at the after end of the ship, would be subjected to specially severe stress when she was supported at her mid-length during the passage of the crest of the sea.

How severe these bending stresses are may be judged from the fact that one of the earlier 23-knot ocean liners was proved by exact instrumental measurement, taken for the purpose while she was being driven hard into very heavy head seas, to have a vertical movement at the ends with regard to the midship section of twelve inches. Though this was excessive, it does not prove that the ship was structurally weak; for in such vessels the deep double bottom and the continuous steel upper decks, provide sufficient top and bottom chord material to permit the necessary extension and compression of the steel without exceeding the elastic limit.

In the tank steamer, however, the provision of sufficient girder strength is not so easy of accomplishment as it is in the case of an ocean liner with its plurality of upper steel decks. The tank steamer, and in fact all steamers of the Great Lakes type that are built to carry heavy freight in bulk, consist, throughout the greater part of their length, of a double bottom, the two sides and a single upper deck; this last being pierced by many hatches, some of them of very large size. Much ingenuity has been shown in the endeavor to make these long shallow ships sufficiently strong to carry their heavy load safely through heavy seas.

Great technical interest will attach to the investigation of the accident to the "Oklahoma." Say what we will, this accident must necessarily arouse a certain degree of distrust of present tank-steamer construction; and it is sincerely to be hoped that sufficient evidence will be gathered from the survivors to enable the naval architect to determine just where the rupture commenced, and exactly in what manner the ship's plating tore asunder. It is important to know whether the fracture followed a zigzag line along the side plating or whether, as Mr. Holmes has suggested, it followed a vertical line of rivet holes where a transverse bulkhead was attached to the hull.

The Kahn Act and Foreign Exhibitors of Patented Articles at the Panama-Pacific Exposition

NO remarkable prophetic gift was needed to foretell the storm of protest that has followed the approval of the Kahn bill—a measure which is intended to protect foreign exhibitors at the Panama-Pacific Exposition from patent and copyright infringement by Americans, by enabling a foreigner who has patented his product in his home country to obtain absolute protection in this country by the mere filing of the necessary papers, without any search as to novelty and without complying with any of the rigorous requirements of the American patent law. The bill was so clearly unconstitutional that few thought it possible that it would ever pass. And yet the impossible has happened.

The defects of the measure are so apparent that as it stands it cannot endure the legal scrutiny of the United States Supreme Court. It may be doubted whether Mr. Bulkley's painstaking revision will help matters much, although it seeks to remedy the more crying evil of the original by providing that the exhibits shall not enjoy the protection so generously accorded by the Kahn act if they have been "in public use or on sale in this country" or shall have "become the property of another under the laws of this country." While this may remove the absurdity of preventing an American manufacturer from producing an article unpatentable in this country, but patentable in some European countries, it throws upon the foreign exhibitor the burden of proving that his product is indeed patentable in this country and that an American defendant is an out and out infringer. In other words, the foreign exhibitor might just as well apply for a United States patent in the regular way if he is to enjoy any benefits from the Kahn act as Mr. Bulkley seeks to amend it.

It is difficult to understand why the exposition authorities should have been so deeply concerned in the protection of foreign exhibitors. We are not aware that any foreign country has ever extended to exhibitors of other nations at any exposition the rights and privileges extended by the Kahn Act. Furthermore, a foreign manufacturer who exhibits at San Francisco no doubt does so for commercial reasons. If he hopes to interest Americans in his product by availing himself of the opportunities accorded him at San Francisco, there seems to be no valid reason why he should not protect himself in the manner prescribed by the constitution and the patent laws of this country.

As they now stand, our patent laws are probably the most generous of their kind in the world. From the very first the United States of America set an example to the world in freely according to foreigners the same measure of protection for patentable inventions as to Americans. If there were any possible discrimination against foreigners, there might be some excuse for the Kahn Act; but as matters now stand, the Act places the foreign manufacturer of an invention which he has patented in his own country, but which for good reasons is unpatentable in this country, in a far better position than his American rival.

Nothing short of the absolute repeal of the Kahn Act can be justly condemned. Not only is it unfair to Americans, but it deals unfairly even by the foreigners whom it is supposed to protect. Of the unconstitutionality of the Act as it now stands there can be no question. Yet the exposition authorities are apparently lulling foreigners into the belief that they may safely exhibit inventions in San Francisco, which in the eyes of the Patent Office and of our courts would be public property. What will be their astonishment when they seek to apply the Kahn Act to their special cases and find themselves thrown out of court? Will we not be accused of double dealing? The governments of Europe have not all unanimously decided to participate in making the Panama-Pacific Exposition a success. A general feeling is rife that there have been too many expositions. If the Kahn Act ever comes up for judicial construction and is declared unconstitutional and void, it may be doubted if foreign governments will look with favor upon future American expositions.

The Sun-power Plant in Egypt

A RECENTLY prepared report on the sun-power plant at Meadi, Cairo, gives some important data on this highly interesting development.

A series of trials was carried out under favorable weather conditions, in which, we are told, the area of sunshine collected and utilized in heating the five boilers was 13,269 square feet, and the maximum steam pressure generated was 1.1 pound per square inch above atmosphere, the minimum pressure 1.0 pound per square inch.

The average amount of steam generated per hour throughout the trials was 1,160 pounds. The maximum amount of steam generated during any one hour was obtained between 1:10 and 2:10 P. M. on August 22nd and amounted to 1,442 pounds, while the minimum generated in any one hour was obtained between 3:15 and 4:15 P. M. on August 25th, and amounted to 886 pounds.

In order to obtain the best results from steam at the low pressure of the sun-power system, it should be utilized in a suitable steam engine. A condensing engine especially designed for use in connection with the sun-power boilers was tested in 1912, and when it was developing 97½ brake horse-power the steam required at a pressure of 1 pound per square inch above atmosphere was only 22 pounds per brake horse power.

Had the installation at Meadi consisted of nine sun boilers instead of five they would have produced enough steam to have kept this engine running and developing an average of over 95 brake horse-power throughout the twelve and a quarter hours occupied by the trials.

What progress has been made during the last two years can be seen by comparing the results here quoted with those obtained at the Tacony (Philadelphia) plant in 1911:

The total area of sunshine collected by that plant was 10,296 square feet. The average amount of steam produced throughout a 4-hour trial on August 10th was 693 pounds per hour. The mean steam pressure during the four hours was 1.2 pound per square inch *below* atmospheric pressure.

The most important figure, however, and one which is closely comparable, is the steam produced per hour per square foot of sunshine collected. The maximum for the Tacony boiler was 0.090 pound per square foot per hour, whereas the corresponding figure for the Meadi boiler was 0.12 pound per square foot per hour, which is equivalent to an increase of 33 1/3 per cent, a very gratifying improvement, especially when it is borne in mind that the mean steam pressure at Tacony was 2 pounds per square inch less than at Meadi.

That this improvement is not entirely due to the generally better climatic conditions of Meadi as compared with those of Tacony seems to be indicated by the fact that the Tacony result was obtained when the mean temperature in the shade was 90.4 deg. Fahr. and the mean humidity 45.5 per cent, while the Meadi result was obtained when the shade temperature was 95.5 deg. Fahr. and the humidity 35 per cent. Hence a considerable portion of the 33 1/3 per cent increase of output may fairly be attributed to improvements in the design of the plant.

These results seem very encouraging, and we may express the hope that this pioneer undertaking may meet with the success that it deserves.

A Radio Manual will shortly be issued by the United States Signal Corps, dealing with the installation and operation of radiotelegraphic apparatus, especially field stations, and intended primarily for the guidance of the regular and militia forces. After much experimenting the Signal Corps has devised field radio outfits that will probably not be materially modified for some years to come. A radio pack set, which is carried by 3 mules, can be put in operation in two minutes, weighs 370 pounds, and under service conditions has a range of 25 miles. A wagon set of 2 kilowatts power has a range of more than 200 miles. It is made up of a pintle-type wagon, drawn by four animals, the rear cart containing the power plant and the front the operating apparatus.

Electricity

Wireless on the Great Lakes.—According to the Department of Commerce, the disastrous storm of last November on the Great Lakes furnished a signal illustration of the necessity of equipping lake vessels with wireless telegraphy. All vessels so equipped received warning of the storm and sought shelter, while 19 American vessels without wireless were lost. About 50 vessels are now preparing to add wireless telegraph apparatus to their equipment.

Large Plant for Producing Carbide and Nitrate of Calcium.—An electro-chemical works which ranks among the large Swedish plants of its type, has been installed near Johannesburg, and it is designed to turn out carbide and nitrate of calcium upon a new process invented by Engineer F. Carlson. It is stated that there are now running on this principle, four 400-kilowatt furnaces using single-phase current, for the production of carbide. As to nitrate of calcium, which is employed for fertilising purposes, there are in use six furnaces on the 3-phase system of 2,600 kilowatt size. In order to secure what current the present plant demands, a large hydraulic plant is erected at a cost of over a million, and it operates by power from the Ljungan stream.

Largest Electric Hoist in America.—One of the largest electric hoists in the world, and exceeded only by a few in South Africa, will be installed in the Granite Mountain shaft of the North Butte Mining Company. The hoist will have a capacity of 300 tons per hour hoisted from a 2,000-foot level, or 200 tons per hour from a 4,000-foot level. The shaft is now approaching the 2,900-foot level. The hoisting drum, 12 feet in diameter, will be driven by a direct-connected electric motor supplied with power from a motor generator set provided with a 50-ton flywheel. The flywheel will give up some of its stored energy to supply the peak load drawn by the hoisting motor. The induction motor of the generator set will have a continuous rating of 1,400 horse-power and the hoisting motor will have a maximum intermittent rating of 4,500 horse-power.

Turbine Progress in Europe.—We note that the Brown-Boveri works is engaged in constructing a turbine group of no less than 40,000 horse-power size, it being intended for the Mark electric station in Westphalia. The alternator of this group is designed for 10,000 volts three-phase and 50 cycles and operated at 1,000 revolutions per minute. The turbine works on superheated steam at 350 deg. Cent. and 13.5 atmospheres pressure at the inlet, the entire group measuring about 33 feet long. Among other large turbines of this type we may mention the 30,000 horse-power alternator lately set up in the Reisholz plant near Düsseldorf, and a similar group is now building at the same works for an electric plant near Cologne. It is expected that steam turbines of as high as 50,000 or 60,000 horse-power will be constructed as the next move.

Electrolytic Extraction of Copper in Chile.—German electrical apparatus is now installed in a plant located in Chile for extraction of copper from the ore, and the works are said to be operating quite successfully at present. It makes use of the new Siemens-Schuckert electrolytic process. The electric station is situated at Cobija on the coast and 180 miles from the copper mines, which are inland, and the current is sent to the copper extraction plant at the mines by a power line. The electric station is steam operated, and is equipped with 16 boilers which are fired by oil fuel. Four steam turbines are each coupled to an alternator of 15,000 horse-power size which delivers 5,000 volts, and step-up transformers raise the voltage to 110,000 volts for operating the power line. At the copper mines is a substation containing motor-generator sets of 3,000 horse-power size which receive the current from the line and convert it to 250 — 190 volt current for use in the electrolytic tanks.

Electrifying Railways in Norway.—In Norway the government proposes to carry out quite an extensive scheme for applying electric traction to the railroads. According to an official report as to hydraulic resources, the state already owns enough water power to serve for nearly all the railroads in the south and west of the country. However, as it is intended to go into the matter on as large a scale as possible, the government is seeking to purchase as many falls as possible in order to obtain the needed amount of power. A great outlay of capital will be needed to carry out the extensive railroad project. Among the principal railroads are seven lines, including two from Christiania to the Swedish frontier, and others from that city to Gjoevik and Drammen. For the high-tension power lines from the turbine stations to railroads, including also the substations, the outlay is $12,000,000. Notwithstanding the considerable cost of adopting electricity for the railroads, it is expected to secure much economy in operating these lines. Parliament lately decided to begin the first work on the Christiania-Drammen railroad line. Norway is so rich in hydraulic resources that there is little excuse for the employment of any other power.

Science

An Institute for Bibliographic Research, the first of its kind in America, will soon be established in Chicago, if the plans of the Bibliographical Society of America are carried out.

A New Product of Seaweed, the invention of which is announced from Liverpool, is called "algin," and is used in the manufacture of non-inflammable cinematograph films and in the treatment of paper to make the latter water, flame and germ proof. Algin is said to be odorless.

An Institute of Oceanography, with a fine aquarium, is to be established at Ste. Adresse, a suburb of Havre, in a large park overlooking the bay of the Seine. It is hoped to have the institute open in time for the scientific congress to be held at Havre in the autumn of 1914. A feature of the institute's work will be practical instruction to fishermen.

Urotropine as a Preservative of Caviar.—A consular report states that of about 1,400,000 pounds of caviar obtained each year by the Astrakhan fisheries, approximately 75 per cent is exported, and the only preservative thus far found to keep the caviar fresh is urotropine, which is added in the proportion of 1 to 1,300, and is claimed not to be injurious to health.

The Discovery of Minor Planets still goes on apace. During the year ended June 30th, 1913, 67 of these bodies were given provisional numbers, though 5 of these subsequently proved to be old members of the asteroid family. Of the remainder, 19 were discovered at Heidelberg, 7 at Johannesburg, 9 at Neuchâtel, 11 at Simeis, 3 at Vienna, and 13 at Winchester. All minor planets from No. 1 to No. 727 have now been named.

A Plague of Wild Horses.—The Canadian government has been urged to take measures for checking the depredations of wild horses in the Peace River country in western Alberta and eastern British Columbia. The horses have been making raids on the ranches, killing many domestic horses and leading away valuable mares which had been imported at considerable expense by the settlers. The culprits are said to be the descendants of horses abandoned during the gold rush to the Yukon territory in 1897-98.

Soda Deposits of Lake Magadi.—The American consul at Zanzibar reports that Lake Magadi (spelled "Maggadi" on British official maps), lying southwest of Nairobi, in the southern part of British East Africa, is an almost inexhaustible source of soda. As the deposits are removed they are replaced through soda springs from which crystals of soda are constantly forming. A 95-mile railway has recently been built to connect this lake with the Uganda Railway, and a factory for preparing the soda is to be built at the lake. It is estimated that 160,000 tons of the worked product will pass over the railway to the sea. The soda deposits cover 30 square miles.

Lake Erie Outlet.—The International Waterways Commission has published its final report on the proposal to establish a submerged dam or weir at the outlet of Lake Erie for the purpose of raising the water in all the Great Lakes except Ontario. Its cost would be about $3,000,000, and the Commission unanimously recommends that a treaty be entered into between Great Britain and the United States providing for its construction. The report states that the level of the lakes has been appreciably lowered by the Chicago Drainage Canal and the Erie Canal. To illustrate the importance of this question, it is pointed out that the freight boats on the lakes are built to the greatest capacity the depth of harbors and channels will permit, and that every added inch of water means an increased capacity of 85 tons in these big vessels.

The Tsangpo-Brahmaputra Question Again.—The tantalizing question as to the nature of the connection between the Tsangpo River, of Tibet, and the Brahmaputra, of Assam, is not yet fully settled, despite the large number of explorers who have tried to clear up this celebrated mystery. It will be recalled that when a punitive expedition was sent by the British authorities against the savage Abors a couple of years ago, it was fully expected that the party would complete the exploration of the Dihong River, which undoubtedly forms the connecting link between the two great and well-known rivers (or, properly, parts of a common river), and that white men would then for the first time behold the immense falls supposed to exist where the river breaks through the mountains. Although the expeditionary force took along a scientific staff for the purpose of exploration, the geographical results of the mission were disappointing. During last summer British officers again explored in this region. One party reached a point on the river four days' journey below the supposed falls, while another penetrated to a point on the Tsangpo six days above the falls, but the falls themselves had not yet been reached when the last news was received in India. The barometric observations of the two parties seem to confirm the great difference of elevation implied by the existence of the falls and cataracts of Tibetan tradition.

Aeronautics

Beachey's Latest "Looping the Loop" Performance.—On December 25th Lincoln Beachey "looped the loop" five consecutive times from a height of 750 feet. Beachey turned a double loop at a height of only 300 feet.

A Monument to Capt. Scheimpflug.—On December 6th, 1913, a tablet was unveiled in Vienna to commemorate the achievements of the late Capt. Scheimpflug, who, as our readers will probably recall, was one of the first to interest himself in photography from aircraft. His photogrammetric camera-gun has been described in the SCIENTIFIC AMERICAN.

A New Army Altitude Record.—A new army altitude record was made at San Diego, on December 18th, by Lieut. H. B. Post, who ascended to a height of 10,600 feet, a gain of more than 2,000 feet over the previous record. The ascent was made in army carrying aeroplane No. 23 from North Island. Lieut. Post made the first 3,000 feet at an average rate of 540 feet a minute.

A French Mail Line by Air Across the Sahara.—The National Aerial League has completed plans for a flight of a flotilla of aeroplanes across the Sahara or Great Desert. They will start from Oran, Algeria, and the final landing will be made at Timbuktu, French Sudan, a distance of 1,400 miles. Pyramids of stones will be placed at intervals to mark the route. If the experiment proves successful the establishment of a regular air mail service will be considered.

Naval Aeronautics.—A definite programme for the development of aviation in the navy has been decided upon and will be put into operation at once. A naval aviation school will be established at Pensacola, the battleship "Mississippi" will be assigned to that station for use by the navy aviators, and during the winter practical experiments and training of naval officers in the operation of aeroplanes will be carried on. Flights will be made from the deck of the "Mississippi" and other experiments conducted in developing the use of the aeroplane in connection with battleships.

Vedrines' Flight from Paris to Cairo.—The flight of Vedrines from Paris to Constantinople in five stages and his supplementary journey to Cairo in three more stages must stand as one of the most remarkable achievements of that remarkable aviator. He defied the German authorities, who had refused him permission to fly over German territory (incidentally highly irritating German nerves by circling over a fortress) and braved the high winds of the Taurus Mountains, which proved the undoing of Daucourt. How far Vedrines will push on in his expressed intention of attempting the encircling of the globe remains to be seen. Invitations to fly to this or that point reach him almost daily.

A New Giant Biplane.—The Russian aviator and designer, Sikorski, whose huge aeroplane was described and illustrated in these columns last year, has now built a still larger machine, weighing no less than three tons and a half. It is said that the new machine is propelled by four motors of 100 horse-power each; but this is also the engine power of the old machine. The new biplane is said to have a carrying capacity of twenty people, and that cabins with sleeping accommodations are provided. On the trial trip the machine is said to have risen in the air after a run of 100 yards and to have circled the grounds without difficulty. The SCIENTIFIC AMERICAN hopes to publish a detailed account of the machine.

The Signal Corps Aviation School.—Teaching army officers the subjects of aero-mechanics and aeroplane design has something picturesque about it if we may judge from the account which one of the instructors gives us. When the clock strikes, the pupils flock from all corners of the sky and volplane down to the instructor's pulpit and blackboard in a great white tent. They sit erect and still as mice, smoking as they listen, while the dogs sleep at their feet. A beginning has been made in what may develop into regular and systematic annual courses of lectures accompanied by problems and experiments. The instructors thus far chosen are Dr. Alfred F. Zahn, Prof. Durand and Dr. Humphreys.

Marking Military Aircraft.—According to Major Bannerman-Phillips in the *United Service Magazine*, "it was announced some time ago that fresh orders would be issued shortly by the French Ministry of War regarding imposition of distinguishing marks on military aircraft." In future all military aeroplanes will bear on the under surface of each wing (the lower wing in the case of a biplane) a tricolor cockade one meter in diameter. Dirigible balloons, on the other hand, will bear on the under surface of the front of the balloon its name in large black letters. At the rear end of the balloon will be the national flag with a tricolor pennant immediately above and on the same halyards. The dimensions of the pennant are: height, half that of the flag; length, one and one half times the length of the flag. Free balloons owned by the military service are to have from one of the suspension cables the national flag, and on the opposite cable a tricolor pennant."

X-Ray Photographs of Microscopic Objects

How They Are Made by the Goby Method

By the Paris Correspondent of the Scientific American

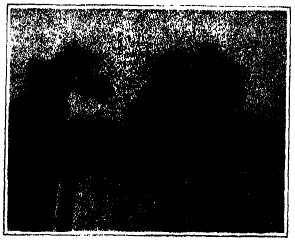
THE new apparatus made by the French scientist Pierre Goby opens up an attractive field of research which he calls micro-radiography, from the fact that it is now possible to obtain X-ray photographs of the internal structure of microscopic objects As it appears that this is the first practical application of the X-rays in microscopic work, the new method is attracting much attention among scientists, as it is recognized that it will contribute greatly to our knowledge of minute animal life. Biological and kindred sciences have recourse to the microscope at every moment, but it often happens that specimens are opaque, hence the necessity of making sections of the objects in order to observe their internal structure, but this is well known to be a great disadvantage from the fact that nothing is now left of the exterior of the objects under examination, and besides, the systematic study of sections of an object requires numerous and patient observations in order to reconstitute the *ensemble* from the various details While the use of the X-rays has been valuable for observing the internal structure of large objects such as can be seen and photographed directly, the fact that such rays do not obey the laws of refraction and cannot be used with lenses makes it impossible to apply them directly for making micro radiographs.

The problem is solved by M Goby in an ingenious way by his new method which consists in applying the minute object directly upon a photographic plate and sending upon it a beam of rays which are as nearly as possible perpendicular to the plate, thus avoiding all penumbra and giving a record of all the finest details of the object in its internal parts with such precision that after developing, the minute images thus obtained can be enlarged from 15 to 45 diameters in an ordinary micro-photographic apparatus On the other hand, the quality of the enlarged image naturally depends upon the fineness of grain of the photographic plate after developing, and he therefore uses a plate which has as fine grain as possible and at the same time is sensitive enough to allow of a reasonably short exposure.

The construction of the apparatus is shown in the photographs, the general idea being to place the minute object directly upon the film side of a small photographic plate upon the base of the instrument and within a dark chamber of cylindrical shape. The X-ray bulb placed at the top of the device sends down the rays through a central tube which serves to direct the rays nearly vertical upon the object and the photographic plate in order to make a "shadow" upon the latter, and the main point in the present makeup is to produce rays which fall as nearly perpendicular as possible to the object and plate, for were this not done and the rays were diffused in various directions, it is evident that the record made on the photographic plate would be blurred by such irregular rays and the minute and delicate outlines of the internal structure would be confused and lost. It would then be impossible to enlarge such a plate so as to obtain a view such as would show all the details to the naked eye.

The dark chamber is made up of a pair of large sliding metal cylinders, the upper one carrying a sliding tube through which the rays pass. The whole device is held at one side by a telescoping support with ball and socket joint so that the apparatus can be raised out of the groove on the bottom plate and turned up so that the observer can look through the lower end of the tube to see that the rays come through properly. On the top is a support for holding the X-ray bulb, provided with rack-and-pinion adjustments so as to set its position at the proper distance from the tube. Turning up the device, the observer sees that the rays fall through the tube as is required, and after adjusting for this purpose, he brings down the dark chamber upon the base, all light being thus cut off from the inside. Previous to this he has placed the specimen upon a small square photographic plate, preferably of a fine grain, and directly in contact with the sensitive surface without putting black paper between the two, so that the resulting image or shadow is very sharp and clear. The rays are directed along the axis of the tube by using a small diaphragm at the top, using as a finder a narrow tube near the bottom, so that a vertical beam of the rays comes out of the tube upon the object below in order to make the photographic impression on the plate.

The X-ray bulb can be adjusted in position so that its rays fall directly on the plate.



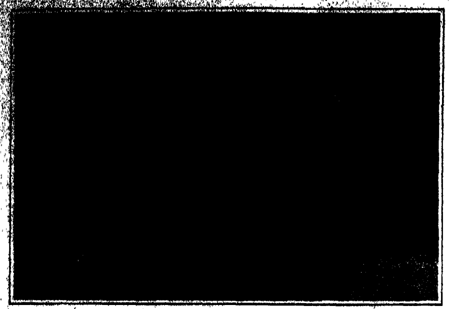
The general idea is to place the minute object directly on the film side of a photographic plate.

The upper diaphragm disk of the apparatus is constructed entirely of very thick lead so as to cut off the passage of the rays except through the small central hole, and below it is a disk, serving as a shutter to stop off all ordinary light rays which might leak in from the top, but allowing the X-rays to pass through. At the lower end of the tube is a finder device which consists essentially of the very narrow metal tube held between the two permeable disks. Below this is a small fluorescent screen fitted into the tube end and covered with a plate of lead glass in order to protect the operator's eye. To make sure that the ray falls just in the center, the X-ray bulb is moved about until the small luminous spot appears surrounded by a small black circle which is the shadow of the small tube and indicates that the rays are quite vertical. Then the finder as a whole is drawn out of the main tube and the apparatus put in the vertical position so as to cover the object as above stated. This latter operation is carried out in the dark room when the photographic plate is put in, the X-ray bulb being now out of action. Then the bulb is set working on the electric current for the required time, varying with the transparency of the object and lasting from one to three minutes. The quality of the rays produced by the bulb can also be varied to suit the case by the use of well known methods. It is also possible to widen or narrow the field of the rays upon the photographic plate by approaching the tube to the X-ray bulb or by lowering it, the tube being made sliding to this effect.

The New Buildings of the Paris University

OWING to the lack of room in the Paris University buildings for the departments of chemistry and researches upon radium, it was decided to erect commodious quarters for such work. The new buildings in the Latin quarter are now almost finished and contain well fitted laboratories and halls. The largest building is the Chemical Institute, which covers an extensive space and is said to be the most considerable in Europe. But it is the new "Radium Palace" which deserves special mention, or more properly, the three buildings which go to make up the Radiology Institute. The first, or "Curie building," is designed for laboratories and courses upon radio-activity, and will be under the special direction of Mme. Curie. Opposite it is a similar edifice built with a subsidy of $80,000 from the Pasteur Institute, to be used for the physiological applications of radium. Between the two is the smallest, but the most interesting building, the "Temple of Radium," which is a veritable strong-box, as it might be called, for holding considerable amounts of radium salts and possibly pure radium. The walls are lined with thick lead sheet, which is needed in order to prevent the emanation of "rays" from passing. We expect to give a further description of these structures when they are fitted up. The present extensive grounds, coming from the demolition of an old convent, will now be an important university center, the first building to be erected here having been the Oceanographic Institute. Another part of the ground will be occupied by the Geography Institution, to be built with a donation of $1,000,000 made by Marquise of Arconati-Visconti, and Architect Nénot is also engaged on the plans for the Institute of Ancient and Modern Art and the Arts Library.

Hogs' Brains are being bought on an extensive scale by a company in Denmark from the abattoirs of that country for use in making lecithin and cerebrin, which are exported to Germany and Switzerland for use in medicine.



A wind shield for cyclists with the aid of which Berthet has beaten some indoor records.

Interior of Bunau-Varilla's wind shield. Through the celluloid window in front the cyclist sees the track.

A Wind Shield for Bicyclists

ETIENNE BUNAU-VARILLA, a son of Phillippe Bunau-Varilla of Panama fame, has devised the wind shield for bicyclists which is illustrated on this page. Cumbrous as the shield may appear, we are assured that a French cyclist, Berthet, easily beat various indoor records from one to five kilometers at the Velodrome d'Hiver in Paris.

The following figures are unusually significant because Berthet was not in particularly good physical condition:

The world's record of 1 minute 9 3/5 seconds for a kilometer with a flying start, made by Perchicot, but not recognized, was reduced to 1 minute 7 seconds. This is also better than Dupré's record of 1 minute 10 3/5 seconds, made in 1911 at Buffalo.

Jaap Eden's record of 1 minute 16 3/5 seconds for a kilometer with a standing start, made in 1896 at Bordeaux and never beaten, was equaled.

The world's record for 5 kilometers with a standing start, made by Verlinden at Anvers in 1910 (6 minutes 56 4/5 seconds) was beaten by exactly 1 minute 10 seconds.

The 250-meter track of the Velodrome d'Hiver was covered in 15 2/5 seconds, or at an average speed of 58.450 kilometers an hour.

Berthet recently raced with Egg under ordinary conditions. He succeeded in beating the time he made in that race with the aid of Bunau-Varilla's wind shield, as the following table shows:

	Against Egg.	With the shield.
1 kilometer	1m. 22s. 3	1m. 16s. 3
2 kilometers	2m. 40s. 4	2m. 23s. 4
3 kilometers	4m.	3m. 31s. 4
4 kilometers	5m. 19s. 1	4m. 39s. 3
5 kilometers	6m. 37s. 3	5m. 46s. 4
Average speed per hour	45.3 kil.	51.902 kil.

The last four kilometers in the foregoing test were covered at an average speed of 53.8 kilometers an hour.

These times were clocked by M. Durand, director of the Velodrome d'Hiver. Although not official, they are, however, instructive.

When it is said that Bunau-Varilla has taken a lively interest in aviation, the origin of his windshield is immediately apparent. Those who have followed the development of streamline bodies in airships, automobiles and aeroplanes, will discern at once that Bunau-Varilla has applied to the bicycle a principle which has been successfully incorporated in their vehicles by the more intelligent designers of airships and automobiles.

The wind shield is fish-shaped and consists of a light frame covered with fabric. When the cyclist is bent over in racing position, he is completely housed within the shield. A celluloid window in front enables him to keep an eye on the track.

It is quite evident that the shield is better than the many projecting surfaces which must be urged through the atmosphere when a bicycle is forced along, each surface stirring up the air and leaving eddies behind. With a properly shaped wind shield the air closes in behind the bicycle and the resistance is so markedly reduced that it is easy to understand why indoor records should be broken.

The Soot-and-Dust-fall of English Towns and Cities; 200 to 2,000 Tons per Square Mile per Annum

How it is to be Measured

By John B. C. Kershaw

THE first of October of the past year marked the commencement in England and Germany of a carefully planned and systematic attempt to measure the amount and to investigate the character of the solid impurities present in the atmosphere of many large towns and centers of manufacturing industry.

Fig. 1.—Diagram showing soot-and-dust-fall of Scotch towns in winter of 1910-1911, based on observations made by Chief Inspector Fyfe of Glasgow.

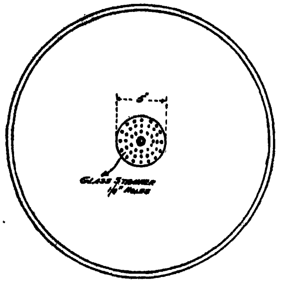


Fig. 2.—Plan of standard soot-and-dust gage, showing catchment area.

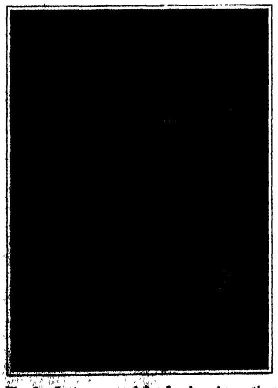

Fig. 3.—Soot-gage used for London observations of 1910-1911, exposed on house roof at Buckingham Gate. S. W.

Everyone is aware that the air of towns contains a much larger amount of soot and dirt than the air of country districts, for even in New York city, the state of the linen and curtains bears effective testimony to the dirtiness of urban atmospheres. But no attempts have been made until recently to measure accurately the relative amounts of impurity suspended in the atmosphere of the more thickly populated districts of town and country. The figures obtained in the tentative experiments carried out in London, Leeds and Glasgow, by different observers, in the years 1910-1912, are of slight value for comparative purposes, since they have been made by different methods, and under different conditions of observation The figures so far, however, have revealed the fact that enormous amounts of solid matter are suspended under ordinary conditions in the atmosphere, and are ultimately washed down with the rainfall upon the buildings and streets. Thus, the soot-and-dust-fall observations already made in London, have given totals varying from 105 tons per square mile per annum at Sutton in Surrey to 650 tons per square mile in the East End, London The experiments at Leeds gave totals ranging from 242 tons in the center of the city to 539 tons at Leeds-Forge, while Glasgow and Coatbridge have exceeded these figures with totals of 1,330 tons and 1,939 tons, respectively. These are staggering totals, when one remembers that this amount of impurity is suspended as a rule in the form of fine dust and soot particles in the atmosphere, and that only after heavy and long continued rain can the air we breathe be considered clean and free from solid impurities. As already stated, the observations made in London, Glasgow and Leeds were carried out under varying conditions by different apparatus and methods, and at the International Conference on Smoke Abatement, held in London in March, 1912, a strong committee was appointed to draw up the details of a standard apparatus and method for measuring the amount of soot and other impurities of the atmosphere. This committee, of which Dr. W N. Shaw, F.R.S., of the Meteorological Office is the chairman, has held five meetings in London, and has drawn up the details of the apparatus and method which have been chosen as most suitable for the observations required A circular letter was issued early in the past year to the public health authorities of all the more important English towns and cities, inviting their co-operation in the work, and it is satisfactory to note that the observations commenced in the following important centers on the first of October, 1913: Birmingham, Bradford, Crewe, Exeter, Hull, Leeds, Leicester, London, Malvern, Newcastle, Plymouth, York and Glasgow The voluntary Association of Steam Users known as the "Hamburg Verein für Rauchbekämpfung" has also agreed to commence observations with the standard apparatus and method in Hamburg. Valuable returns covering a very wide area will therefore soon be available relating to the amount and character of the suspended matter in city and town atmospheres, and with these data before them many of the municipal authorities will have no excuse for ignoring longer the very grave pollution of the air of their own cities.

It may be urged by some critics that, although the figures obtained by the adoption and use of a standard apparatus and method for recording the soot-and-dust fall will be interesting, they will serve no useful purpose, and that the money spent upon the observations could be used more satisfactorily and with greater advantage in other ways. To these critics it may be pointed out that the solid impurities suspended in the atmosphere of all towns and cities are harmful in three ways to those who either by choice or the necessity of earning their daily bread, live and breathe in this vitiated medium

First, by diminishing the amount of sunlight which falls upon the earth, these solid impurities suspended in the atmosphere directly lower the vitality of the human organism, and decrease its ability to resist disease. Cohen has shown that, in Leeds, from 25 per cent to 40 per cent of the sunlight is cut off by the smoky atmosphere In the second place, the soot and dust suspended in the air of all manufacturing towns, enter the lungs and choke up the pores and cells of the lung-tissue, thus hindering that rapid assimilation of oxygen by the blood and discharge of CO_2 and other waste-products, which are essential for the maintenance of health Finally, direct sunlight and pure air are now recognized as the best of germicides. Smoke and dust, by diminishing the sunlight and defiling the air, therefore promote bacterial life, and are thus helpful in the propagation of all infectious diseases.

In view of these scientific facts, it is evident that any series of observations which will place definite figures for the degree of pollution of town air in the hands of city authorities, and thus enable them to compare the purity of their own atmosphere with that of other towns of similar size and population, will give a real incentive to improvement—a stimulus which could be obtained in no other way. When for example, Glasgow can show by its records a cleaner atmosphere than Liverpool, or Pittsburgh than New York, or Manchester than Leeds, the upward progress will have commenced in earnest, and each city and town will strive to excel its rival in this competition for a purer air. These standard records of atmospheric pollution will also be useful for determining the progress of the district as regards the purity of its atmosphere, when the observations have been continued in one town or city over a period of some years

The final proof that the observations are worth making and will prove of permanent value is, that the present head of the British Meteorological Office (Dr W N Shaw) would not have accepted the chairmanship of the Air Pollution Committee, unless convinced of the importance of the work which it is proposed to carry out.

The following is the official description of the apparatus which has been selected for making these observations, and of its method of use: The principle of the apparatus and method is the collection of the rainfall in an enlarged rain gage, and the separation from the collected water of the solid impurities which it carries down and retains either in suspension or in solution. The standard gage consists of a galvanized iron stand, supporting a circular enameled iron gage vessel of four square feet superficial area. Projecting above the gage vessel is a wire screen open at the top, intended to prevent birds from settling on the edge of the vessel The gage vessel is conical at the bottom and communicates, by means of a glass tube and rubber connection, with a group of three or more bottles connected together, and designed to hold one month's rainfall The rain and deposited matter falling on the gage are collected in the bottom, and are removed once a month for analysis Fig. 3 shows the gage used for the investigation of London's soot-fall, carried out in 1910-1911 The results of this investigation were referred to in the introduction to this article.

The instructions for use of this standard gage state that it is to be placed if possible on the ground-level in open spaces free from abnormal dust and wind eddies, and that the bottles containing the water and deposit are to be removed on the last day of each month, and replaced by thoroughly clean empty bottles Before removing the bottles, a brush and a rubber squeegee of standard pattern are to be used to remove any adherent matter. A chemical analysis of the water and deposit is then to be made by a standard method, details of which will be provided by the committee, and a report of the results obtained is to be sent monthly to the central office of the committee in London. At the end of twelve months, the Central London Committee will tabulate all the observations, and will issue their report giving the figures in an easily comparable form. The method, it may be stated, was only selected by the committee after all the known methods had been subjected to careful examination, and the apparatus described above was considered to fulfill best the requirements of a cheap, durable and accurate means for determining the soot-and-dust-fall of large towns and cities.

As an illustration of what can be achieved by this method, a diagram (Fig. 1) is given above, showing the results of Inspector Fyfe's examination of the air of certain Scotch towns, in the winter months of 1910-1911. Wooden boxes, one foot square and one foot deep, were used for catching the soot-and-dust-fall in these observations, and although this method is crude and inaccurate, it serves to indicate the value of the information that will be obtained, by a more scientific application of the method over a wider area of observation. Fig. 2 represents a plan of standard soot-and-dust-gage, showing the catchment area.

The writer will conclude this article by expressing the hope that the scientists who are in charge of the smoke investigation now being carried out by the Department of Industrial Research of the University of Pittsburgh, may be able to co-operate in this movement for measuring the soot-and-dust-fall of our cities, and that they will commence observations with the standard apparatus and method, in New York, Pittsburgh, Chicago, and other towns and cities of the United States of America at an early date.

The author's thanks are due to the editor and publishers of *The Lancet*, London, and to Chief Inspector Fyfe of Glasgow for their permission to make use of Figs. 1 and 3 for the purpose of illustrating this article.

The Renewed Siege of the Antarctic

AFTER a lull following the return to civilization last year of the British and German expeditions, as well as the greater part of Mawson's Australian expedition, a vigorous renewal of south polar exploration is now on the cards. It is practically certain that three large and well-organized parties will sail for Antarctica this year, and there is talk of two or three others. The fact that nearly three thousand men have applied for places on one of these expeditions, many of them offering to pay handsomely for the privilege of facing perils and privations in the frozen wastes, is one of several tokens of the immense vogue that polar exploration is now enjoying, and signal proof that the love of adventure, which, whether confessed or not, is the mainspring of all such undertakings, is not decadent among men.

Recent additions to the Antarctic map have been made chiefly on the side of the continent nearest to Australia and New Zealand, where the region from the Ross Barrier and Queen Victoria Land southward to the pole has been explored by Scott, Shackleton, and Amundsen, and the long coast of Wilkes Land by Mawson and Wild. The principal operations of the new expeditions will be conducted elsewhere.

A British expedition under Mr. J. Foster Stackhouse is planning to explore King Edward VII Land, which lies on the east side of Ross Sea, and as much as possible of the coast extending eastward toward Graham Land—at present a long blank on our maps. Stackhouse regards his undertaking as a continuation of the work carried out by Capt. Scott, and has aroused some rather gratuitous criticism by his use of Scott's name in support of his plans. His contention is that his project was originally discussed with and approved by Capt. Scott, that he has acquired the ship "Discovery," built for Scott's first expedition, and that he proposes to explore a land which Scott discovered.

A large Austrian expedition, commanded by Dr. Felix König, an experienced mountaineer and polar explorer, will go south on the ship "Deutschland," which was used by Filchner's expedition. This party proposes to continue Filchner's exploration of the coast of Weddell Sea, and to establish a base on land, from which three long sledge journeys are to be made by different sections of the expedition; viz., to the south, east and west. No special emphasis appears to be laid upon reaching the pole, the principal object of the expedition being to explore thoroughly the now little-known Weddell Sea side of the continent.

The third expedition definitely planned for 1914 will be commanded by Sir Ernest Shackleton, and proposes to attempt the hazardous feat of crossing the Antarctic continent from the Atlantic to the Pacific coast, a distance of about 1,700 miles—as far as from New York city to Dallas, Texas. Shackleton himself has described his projected crossing as "a longer journey than to the pole and back and infinitely more difficult, because we shall always be advancing over new ground, with no depots to draw upon" It is possible, however, that the party will not have to depend entirely upon its own resources during the latter part of the journey, as it is planned to have an auxiliary expedition land on the coast of Ross Sea and sledge southward along a previously arranged meridian as far as latitude 83, if possible, to meet the explorers coming from the pole. The expedition will have two ships, driven by oil fuel, for the main and auxiliary parties respectively. The sledges, which will perhaps be constructed of steel tubing, will be drawn by dogs, except two, which will be driven by aeroplane propellers. Other novel features of the equipment are under consideration The expedition goes south next autumn, and Shackleton hopes to complete the transcontinental journey by the following spring, though the entire expedition is not to return before the spring of 1916. It is to be hoped that he will be more lucky than Filchner, who undertook in 1911-13 to make a very similar journey over the same route, but never even succeeded in getting ashore on the Antarctic continent.

At the International Geographical Congress, held last April, Dr. W. S. Bruce outlined the plans of a Scottish expedition, which also proposes to cross Antarctica from Weddell Sea to Ross Sea. A lack of funds appears to have prevented the maturing of this project, and, as far as we know, no announcement has yet been made as to when the expedition hopes to sail.

In regard to the extraordinary announcement in recent press dispatches that Louis de Rougemont, "the veteran explorer," will lead a large expedition to the Antarctic under the patronage of the Australian government, the only comment that need be made for the present is "Interesting if true." De Rougemont achieved notoriety in the year 1898 by a story of picturesque adventures in Australia, narrated at a meeting of the British Association, concerning the veracity of which a long controversy raged in the magazines and newspapers of the period.

A Modern Battle-practice Target

THE naval target shown on the cover of this issue gives a near view, which enables the reader to get a clear conception of the construction and various details of an object which ordinarily can be viewed by the layman only from a distance of many miles.

It will be noted that the target is of simple and rather crude construction. It consists of a submerged hull carrying a comparatively light superstructure. The superstructure of the target shown is thirty feet high by sixty feet long. Its height is therefore approximately the average height of a battleship above its water-line. The length is about one tenth of the overall length of a modern dreadnought.

The hull, or raft, is built up solid of 12-inch by 12-inch timbers, strongly bolted together; and it measures in length over all about 110 feet, in width about 5 feet 6 inches, in depth about 15 feet. The bottom of the hull is ballasted and to each end is attached a heavy chain bridle, to which is made fast the towing hawser.

The superstructure above the deck of the raft (the latter is ordinarily about awash) is the target proper. It consists of a number of stout uprights, across which is nailed a series of horizontal battens or strips of wood. Over this is drawn a net of rather coarse mesh, which is hauled up to the top of the uprights and then drawn taut by blocks and tackle attached to the bolt rope at the bottom of the net and to the deck.

The target is towed, usually, by a battleship, the distance from the ship to the target being ordinarily between three and four hundred yards. The ship that does the firing steams past the target, either in the same or the opposite direction to that in which the target is being towed, and "lets fly" at it. On the quarter deck of the towing ship is a group of officers who observe the fall of the shot. The splash of these is photographed, and, latterly, moving picture machines have been utilized to show exactly what takes place. After a ship has fired, the "seamen" lower a boat, row over to the raft, and take down the net, which is then spread out on the deck of the firing ship and the number of holes is counted.

The Current Supplement

IN this week's issue of the SCIENTIFIC AMERICAN SUPPLEMENT, F. Donaldson discusses the proper methods of sinking and lining shafts so as to avoid heavy fixed pumping expense after the completion of the mines.—G. A. Cromie, superintendent of trees, New Haven, reports on an unusual case of electrical injury to street trees.—A comparative estimate of the cost of power from coal and from solar radiation, based upon the performance of the plant in Egypt is published in this issue.—R. Thurston Kent, writing on economies in shop transportation, shows how loss of time between machine operations can be reduced by judicious equipment.—H. C. Plummer contributes an excellent article on the "Soo" Canal at the outlet of Lake Superior, where the world's greatest inland traffic by water passes.—F. A. Perret discusses the causes of the ascent of lava from the interior of the earth.—Most useful information on the causes of the bursting of flywheels and the proper methods to be adapted to provide safety against such accidents will be found in an article dealing with this subject.—H. L. White discusses the influence of bran extracts on the baking qualities of flour.—F. Oswald writes on the Sudden Origin of New Types.

Effect of Hydrochloric Acid on Silica

SOME very singular and unexplained effects of hydrochloric acid upon silica are brought out in M. Armand Gantier's paper recently read before the Académie des Sciences. In his recent experiments on this subject Gantier finds that the effect of the acid varies widely according to the form of the silica. In the shape of rock crystal, the acid attacks it but slightly. Some action can be detected when the crystal is cut parallel to the axis, but it is practically nothing upon the surface when cut across the axis. The reason for this difference is unknown as yet.

Radium in Cancer

Its Scope of Usetulness and Its Limitations

By Worthington Seaton Russell, M.D., Research Fellow and Chief of the X-ray Department, New York Skin and Cancer Hospital

Great have been the triumphs of medical science in recent years. Some of our worst foes—diphtheria, typhoid fever, small-pox, etc., have yielded to methods based upon modern bacteriology. Unfortunately the methods so successfully employed in the instances cited, fail completely in our fight against two of the worst enemies of mankind—tuberculosis and cancer. What then are we to do? Are we to fold our hands in our laps while awaiting the deliverer who shall free us from these bonds?

There is an old adage that prevention is better than cure. Where the prospect of a cure is at the best very uncertain, this truism acquires special significance, and thus the warfare against tuberculosis and cancer has been largely a warfare of education—the dissemination of knowledge regarding the causes and modes of transmission of these scourges. In the case of tuberculosis this mode of attack has been most fruitful of results. It has been the hope of the medical profession that something at least could also be accomplished in this way in the warfare against cancer. The people have been warned of the nature of the first indication of cancer and of the deadly danger incurred by delay in consulting a competent surgeon, or by failing to follow his advice when the knife must intervene.

It is to be greatly regretted that much of the good that such a campaign may have accomplished, must have been undone by the sensational newspaper accounts and scare headlines which have recently proclaimed alleged healing powers, little short of miraculous, for radium in the treatment of cancer.

The truth is that radium has for many years past been employed as a remedial agent against certain superficial growths somewhat akin to cancer, and that some good results have been obtained. But the field of usefulness for the substance has been quite limited, and there is at present no basis for the belief that recent developments so glaringly displayed in the newspapers will bring any immediate advances of a startling character. At the best many months, if not years, must elapse, before any certainty can be reached, and before the general public can profit by a new remedy which has not yet passed out of the experimental stage. In the meanwhile many may be misled by a false hope, or may defer the life-saving operation, and incalculable suffering may thus be caused.

It is with these facts in mind that we gladly open our columns to a statement from the pen of Dr. Worthington Seaton Russell, an expert in the field of cancer treatment and research, who, in answer to many inquiries received at the hospital to which he is attached, has made an authoritative statement for publication in the Scientific American *and the Crouse-Irving Bulletin, regarding the present situation.*—Editor.

RECENTLY the daily press has extensively exploited the alleged claims of two well-known members of the medical profession that in radium has been found the long-sought-for cure for cancer.

Articles have appeared in the leading newspapers of all sections of the country, a sample of which I have before me in a clipping from a Syracuse paper with the very positive and convincing headline, "Radium Rays Cure Cancer in Forty-eight Hours," and again in the text, "Cancer is curable and cancerous growths which had resisted every other treatment invented by science *have been cured in forty-eight hours* by the marvelous properties of radium." The italics are mine.

Many "sure cures" for cancer have arisen, owing in great part to the publicity of the subject following an effort of the profession to properly educate the public regarding the importance of an early diagnosis and prompt and proper treatment. There is but one universally recognized cure for cancer—the knife. Those competent to speak authoritatively because of experience with the various methods of treating cancer are unanimously agreed that the early, complete and radical operation is the safest method known to the profession at the present time.

Just as the earnest efforts of those interested in the popular campaign against cancer are beginning to bear fruit and our patients are realising the necessity of operation, comes the positive statement, heralded all over the country, that the dread disease can be cured by radium. The statement is all the more harmful because it purports to come from eminent surgeons, and further because there is an element of truth in what has been reported.

This arousing in a credulous public of the false hope of a cure does incalculable harm. Many sufferers will defer operation until too late, hoping to avoid the use of the dreaded knife, others will spend hard-earned savings in an effort to receive the treatment and many other unfortunate victims will fall into the hands of the numerous quacks whose only claim to radium is in the use of the name in their advertisements. We hear the heart-rending story many times at the New York Skin and Cancer Hospital—the story of the trial, first of this cure, then of that, the eager and anxious waiting for the promised improvement, the consequent despair and the taking up again of the search for the "sure cure," which is never found, until finally the poor sufferer drifts into the hospital, demanding in the name of humanity that "something" be done to relieve the awful suffering. Everything possible is done, but with quite a different outcome than if the patient at the very outset had fallen into the hands of one competent to give advice.

It is not so long ago that we read in the papers of the long line of consumptives, hopeless yet always hopeful, anxiously awaiting the extensively advertised opening of an "institute" for the cure of tuberculosis by the use of a "turtle" vaccine. The doors never opened, and many a sufferer who had spent his last cent upon a long journey had to beg his way home, there to die because the exertion sapped the little vitality he had, and because of the realisation that he had been duped and there was no hope for him. There is no more damnable scheme than that which works upon the credulity of the incurable sick with the promise of a cure.

Now comes the cancer cure by radium. That radium has its field of usefulness in the treatment of certain conditions, particularly of benign growths, is not to be denied, but the statement of enthusiatic advocates that the radio-active material will cure cancer is to be challenged. A proper degree of enthusiasm is laudable, but only when it is tempered with scientific skepticism. Those who have had the most experience with radium are not prepared to state just what the effect is upon cancer. The crucial point is, just what may be considered a "cure" in cancer? We have seen many cases come to the hospital in which the primary growth had disappeared under radium irradiation, but with immense metastases appearing some months afterward. Is it justifiable to record and report such cases as cures? Decidedly no. A case cannot be said to be cured of cancer until five years have elapsed without a recurrence. We are testing many methods of treatment at the Skin and Cancer Hospital, but while we are getting interesting and encouraging results from some, we would not be dealing honestly with our patients nor with those who look to us for our opinions, if we made more positive statements for some time to come. This new method of employing the various radioactive substances in the treatment of cancer should be thoroughly, carefully and scientifically tested by those especially trained to carry on the correct technique, and then, after the proper period of time has elapsed to make the results of real value, a conservative report should be published with an estimate of the worth of the method.

The effect of radium cannot be correctly judged unless comparatively large amounts of high radioactivity are employed and unless the proper technique is used. The employment of a radium salt with a low activity, although the bulk may be large, will not produce results. It is said that one surgeon who was using a considerable quantity of a "radium preparation" without result had it tested by a reliable expert, and was told there was no trace of radium whatever in the material.

For several years Dr. Bainbridge, director of the Cancer Research Department at the New York Skin and Cancer Hospital, and I have visited the Laboratoire Biologique du Radium at Paris, the London Radium Institute and the other institutions using radium, with a view to watching the work they have been doing. The Paris Laboratory is one of the most important, at the same time being the oldest institution devoted exclusively to the use of radium.

We have been using radium at the Skin and Cancer Hospital and are acquiring a larger quantity of a high activity in order to give the method a thorough test.

Drs. Wickham and Degrais, who have been in charge of the Paris Laboratory, read a paper at the International Congress held in London last summer on "Can Radium Help Surgery in the Treatment of Malignant Tumors?" from which paper I will quote some of the writers' views. They advocate operation in all operable cases to be followed by application of radium if a recurrence is to be feared. In those cases in which the growth is difficult of operation they advise radium treatment both before and after the operation. Several investigators have claimed that radium may in some instances convert an inoperable growth into an operable one.

The authors admit that radium has only a local and palliative effect, still in certain cases of cancer a state of apparent cure has remained for several years.

The London Radium Institute was opened in August, 1911, and the first report appeared in the early part of last year. The Institute has the largest quantity of radium of any in the world, and therefore it has not been limited in its work for a lack of the material. The report, therefore, is of value, especially as Dr. Pinch, the medical superintendent, is careful in his attitude toward the method. A total number of from six to seven hundred cases were treated, including 134 patients suffering from epithelioma. Of this number 7 were "apparently cured," 39 decidedly improved, 22 died, 20 showed no improvement, 23 abandoned treatment, 15 received prophylactic raying, and 8 were too recent to be classified. We must exclude those cases that discontinued treatment, those that received the prophylactic raying and the recent cases, leaving a total of 88. Of this number 25 per cent died, while there was cure or improvement in 52 per cent. The report advises operation in all operable cases. The results in cancer of the rectum were not as favorable, although it is claimed that in some instances the growth diminished in size, making it possible to remove the tumor by surgical means.

The most successful treatment was with rodent ulcer, an almost non-malignant affection. Dr Pinch states in the report, "Rodent ulcer is, of all the forms of malignant diseases, the one which is most amenable to the action of radium"

The prophylactic irradiation was employed as a post-operative procedure, and of those so treated only a few showed recurrence. There is a fibrous transformation which serves to arrest hemorrhage and to prevent the dissemination of cancer cells by sealing the lymph vessels.

It must be remembered in analyzing the report that only the most hopeless cases apply for relief and further that Dr. Pinch has classified as "apparently cured" those cases that present a "condition in which all traces of the original lesion have disappeared, in which there is no sign of recurrence and in which the patient is free from any external indication or symptom of the disease."

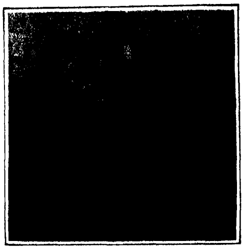
Dr. Knox, in charge of the radium treatment at the London Cancer Hospital, finds that "operation gives the safest, surest and quickest results in all cases of early cancer, but that radium should be used as a useful adjunct following operation." In common with many observers he states that the X-ray may be as useful as radium. The one advantage that radium has over the X-ray is that several tubes containing the radium may be buried in the substance of a growth and left there for a long period of time.

One effect has been noted by some observers, and that is that where a primary growth has been rayed the recurrences which appear on the same site are much more resistant to further action of the radium than was the primary lesion or the secondary tumors which may occur outside the field of the first raying.

I have purposely said nothing of the universal success in the treatment of *benign* conditions, as keloid, nævus, angioma and the like; here one can speak enthusiastically enough, but these facts are well known to the profession.

Except in the case of superficial epitheliomata without secondary involvement and in certain forms of sarcomata, which are not very malignant, there is no warrant in proclaiming radium as a cure for *malignant* tumors.

At the annual meeting of the New York State Medical Society last spring, an enthusiast, in speaking of the use of radium, stated that if he had a sufficient quantity he would transcend the acts of the days of the apostles. I can second Dr. Bainbridge, who replied that he, too, had been fired by the same enthusiasm, but after repeatedly visiting the European centers where radium was being tested, he had seen nothing to prove that we had a new specific remedy for cancer

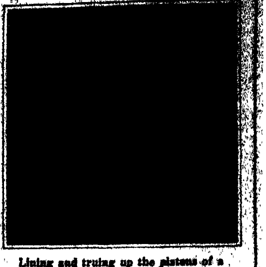


Selecting connecting rods in sets of uniform weight.

Going Through the Shops—III

The Associate Editor of the Scientific American Witnesses Some of the Methods Used in Obtaining Extreme Accuracy in High Grade Motor Cars

By A. Russell Bond

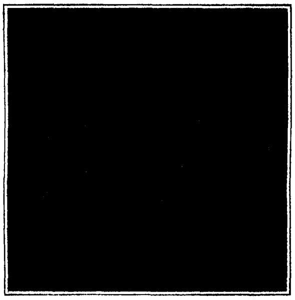


Lining and truing up the pistons of a six-cylinder motor.

THE paper upon which the SCIENTIFIC AMERICAN is printed measures three one-thousandths of an inch in thickness, a measure too small to be observed with the naked eye Yet an automobile manufacturer would hold up his hands in horror if you showed him a piston or cylinder that varied from his stardard by anywhere near that amount Split this paper into six leaves; wrap one of the leaves around a piston of standard measure and you will have increased its diameter by only one one-thousandth of an inch. If then you could insert this piston into its cylinder, the cylinder would probably be rejected as too large, or if accepted, you would be informed that it represents the absolute limit of departure from perfect accuracy. We are accustomed to saying that there must not be a variation of a hair's breadth, believing that to be the acme of accuracy, but a hair's breadth may be three one-thousandths of an inch or more, whereas in the important part of an automobile motor, one one-thousandth of an inch represents the extreme variation permissible in the more important parts of an automobile motor, and some parts have to be ground down to within half of a thousandth of an inch. A common method of testing cylinders is to provide two plug gages, one of them marked "go" and the other "no go" If you pick up these gages you will note that the exact diameter of each is given down to the thousandth part of an inch and that the plug marked "no go" is but one one-thousandth of an inch larger in diameter than the other. The cylinder must be finished to such a size that the "go" plug will enter it and the "no go" plug will not.

An essential part of every automobile factory is the maintenance of micrometers and test gages Thousands of dollars are spent on the gage equipment. A machine cannot be depended upon to cut the work with perfect accuracy, for the cutting tools are bound to wear. Furthermore, a tool, even on a finishing cut, does not leave a perfectly smooth surface. Some manufacturers believe it desirable to leave a mat surface on the inner wall of the cylinder, so that it will hold a film of oil. Other manufacturers believe in grinding both the cylinder and the piston to a perfect fit. While the cutting tools cannot be maintained to a perfect standard of accuracy because of wear, the same is true, although in a far less degree, of the gages Some manufacturers depend upon micrometers and gages made by manufacturers of precision instruments. Others, not satisfied with that, go to the extreme of using master gages with which their micrometers are tested from time to time. These master gages are rectangular pieces of metal, with perfectly true faces and conceded to be the most accurate pieces of mechanical work in the world. Their accuracy is guaranteed to the ten thousandth part of an inch. If two of these pieces be rubbed together to remove the film of air between them they will fit so perfectly as to adhere tenaciously. With such master gages as these, the micrometers are tested from time to time and corrected, and with these micrometers the various gages of the machine shop are in turn tested and kept in perfect condition.

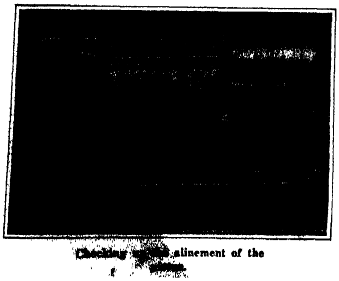
The automobile engine is a high speed machine, and it is absolutely essential to have perfectly fitting parts, for, with the piston reciprocating a thousand times a minute, the slightest looseness would soon develop into serious wear, loss of power and eventually breakage of parts. Of course, no matter how perfect the fit of a piston in its cylinder, it is necessary to use piston rings to prevent leakage of the high pressure gases. To form these rings so that they will bear evenly on all parts of the cylinder while in operation calls for expert designing. One of the accompanying illustrations shows a fatigue test to which certain piston rings are subjected. The piston rings are cut from a cylinder or "pipe." In order to determine whether the piston ring has the requisite amount of resiliency a sample is taken from each pipe and the ring is held open by a suspended weight of about 12 pounds, as shown in the photograph. The sample tested is always the first ring cut, which is looked upon with the most suspicion. The rest of the rings are supported on a peg above the one that is being tested. The 12-pound weight must bring the ring open about 1¼ inches. In that position it is held for twenty-four hours, and then when the weight is removed it must spring back to within 3/16 of an inch. If it fails in this fatigue test, all the rings from the same pipe are thrown out. Not only must there be a perfect fit of the piston in the cylinder, but there must be perfect alinement of the piston in relation to the crank shaft bearing of the connecting rod. One of our illustrations shows a gage used for this purpose. The connecting rod with its piston is supported in the gage with the crank shaft bearing fitted upon a mandrel. A gage lever is then pressed against the side of the piston, and if there is any variation from correct alinement, the variation is shown by a pointer that multiplies the slightest discrepancy. In this alinement gage no variation is permitted, but the pointer must register exactly on the zero point. To determine whether the connecting rod has become bent or twisted ever so slightly another gage is used with which the variation is shown by a multiplying lever, and if it is more than one one-thousandth of an inch the connecting rod is rejected. In order to balance the parts perfectly the pistons and connecting rods of each engine must weigh alike. At the top of the page may be seen a man weighing connecting rods and assembling them in groups of six of equal weight for a six-cylinder engine. At the opposite side of the page may be seen the method of lining and truing up the pistons of a six-cylinder engine.



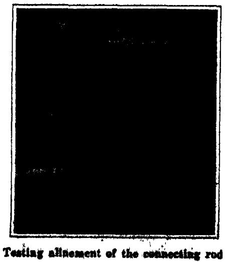
Piston rings undergoing a fatigue test.

The crank shaft is another element of the machine that requires perfect balancing. The shaft is mounted on knife edges, so that if there is any preponderance of weight in any of the crank offsets, the fact will be determined by the turning of the shaft. Not until a shaft has been so balanced that it will maintain itself stationary when turned to any angle, is it accepted for service in an automobile. No less important is the cam shaft. Our illustration shows two tests to which the shafts are subjected. In one of them the bearings of the shaft are being gaged to see if they are true, or if any eccentricity has developed in grinding them. In the other test the relative positions of the cam swells are being gaged. The wheel at the end of the shaft is indexed, and as the different cams are fitted into the gage block the pointer shows on the index whether the swells bear the proper angular relation.

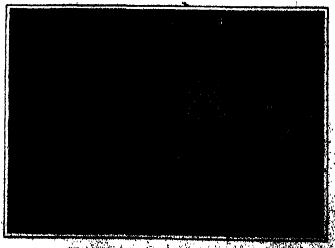
Outside of the motor proper more attention must be given to the gears than any other one part. Spur gears may be cut very accurately, and if necessary ground after being hardened. To test the gears it is customary to revolve them in mesh with a master gear, then the play of the gears toward and from each other, if there be any eccentricity, may be detected by watching an index mark through a magnifying glass. Bevel gears, however, present a more serious problem, for the reason that the cutting of the gears is a complicated process. If the gear is to be hardened after the teeth have been cut, it is sure to be warped out of shape and must be straightened in a press. It is impossible to grind the teeth perfectly true, owing to their tapering shape, and so, if noise is to be avoided, it is customary



Checking up the alinement of the piston.



Testing alinement of the connecting rod bearings.



Weighing the reciprocating parts of a motor.

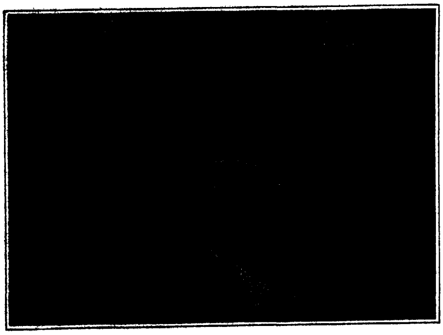
[illegible] they are then [illegible] and passed on to the assembly department.

To avoid noise in spur gears, spiral-toothed gears are largely used. One manufacturer has developed a similar method of overcoming noise in bevel gears. The teeth of the bevel wheel are given a spiral form, so that there is a more continuous engagement of the teeth, and even should the teeth not fit as perfectly as those of a well-matched pair of straight bevel gears they will mesh with practically no noise.

Quiet running is a mark of high-grade workmanship. Special types of engines have been invented to reduce noise, but manufacturers of the standard type find that by using special refinements here and there and a higher class of workmanship, much of the noise that used to be considered essential in the poppet valve motor may be eliminated. One of our illustrations shows the care with which high-grade motors are tested. The engine has gone through the usual test, running many hours under a partial load until all the parts have eased up and are working smoothly. Now it is taken into a room apart, where all noise is excluded. An inspector then goes over the machine with a stethoscope, just as the physician examines the human motor, and he searches for the slightest scraping, throbbing or knocking in any part of the engine which might indicate tightness or looseness. Not until the motor physician is satisfied that every part is working with perfect smoothness is the engine turned over to the assembly department, there to be mounted in the chassis with the transmission gear and run again on a dynamometer test, or on a road test around a specially prepared testing track. Finally after everything has been done to develop latent symptoms of trouble, the body is mounted on the machine, and the finished automobile emerges from the factory.

Hunting for eccentricity in the cam shaft bearings.

Checking up the angular location of the cam swells.



The motor physician hunting for trouble with a stethoscope.

A Folding Wheel-Chair

THERE is no problem in life that is not fit material for the work of the inventor, and many are the situations where the contriver comes to the aid of nature and supplies some comfort or necessity, which tends to lessen the misfortunes of humanity. A case which solves this is shown in the construction of a folding invalid wheel chair. A merchant of New York has an invalid daughter, who, because of an accident, was rendered unable to walk. The girl had at her disposal her father's automobiles, but there was the disadvantage that unless a wheel-chair was provided at the *other end of* the trip the girl could not leave the car, as the only way she could move around from place to place was to be assisted about in a wheel-chair or perambulator. The ordinary wheel-chair was too large and clumsy to go into the body of the automobile, and the girl was forced to remain at home.

The father wrote to various companies to find out whether they would not undertake the construction of a folding chair, such that it could be folded up and stowed in the body of an automobile. None of the companies that manufacture wheel-chairs was willing to undertake such a vehicle, as it did not seem practical.

But by chance, at one of the wheel-chair factories, a new superintendent, in looking over old orders, came upon the letter of the merchant concerning the building of a special folding wheel-chair. The superintendent was at once interested, as it happened that he, too, had an invalid daughter who was unable to walk. Believing that such a folding structure was possible, he obtained permission to attempt the construction of one, the success of which is shown in the following description of the device:

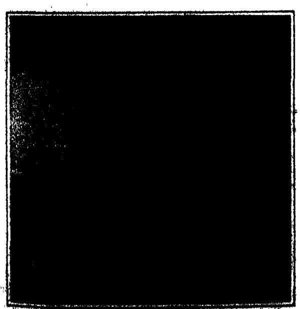
The frame of the chair is made of seamless steel tubing, bent at the corners in graceful curves, and upon this framework is fastened the wooden body, which is made of thin veneer about half an inch thick. The whole body is upholstered in a gray corduroy and is very comfortable when one considers the weight and the space involved. The finish is in maroon enamel and nickel trimmings to match the automobile in which it is carried. The wheels are of the bicycle type with solid rubber tires and ball-bearings. The hubs are made especially narrow to provide for closing into a small space.

Some idea of the folding qualities can be gathered from the fact that the chair folds from 48 inches in height, when "set up," down to 13 inches. From front to rear it folds from 38 inches to about 30 inches, while in width it does not decrease at all, but remains at about 20 inches.

In folding, the chair rolls up somewhat like a bolt of cloth. First of all the sides or arms are folded inward toward each other. Then the back is folded forward and down, and the handle on top of it. Then the braces that hold the wheels are released. The small side boards at the foot are folded toward each other, and the foot-board with the small front wheels attached is folded up against the front of the chair. Then the whole front part of the chair with the foot-board and the wheels, is folded upward and parallel to the back. The large wheels are then closed toward each other and a strap is passed about the whole, and it is ready for carriage.

The weight of the chair is about 70 pounds, which is not any more than the ordinary non-collapsible article. Due to the small space occupied when shut up, no difficulty is experienced by a single person in carrying the device. Folding or unfolding can be accomplished by one person alone in from 30 to 40 seconds.

The chair was forwarded on completion to the merchant, and it fully met with his approval.



Testing gears for concentricity.

Mating bevel gears to run without noise.

Testing noiseless spiral bevel gears.

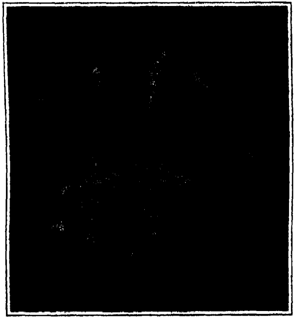
Farm for Jungle Folk

Feeding the Animals of a Zoo and What it Means

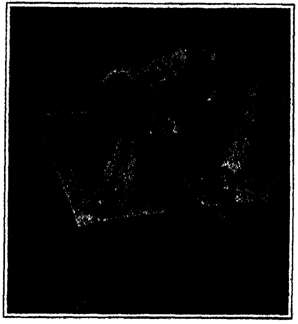
ONE of the most novel and least known agricultural and live stock enterprises probably in New York is the Jungle Farm, where the food is raised for more than five thousand animals, birds, and reptiles, exhibited in the New York Zoological Park. Its output includes everything from young pigs for the big python to lettuce, celery, raspberries, strawberries, honey, etc., for the smaller denizens of the cages. It is located in a secluded valley in Bronxdale, east of the Bronx River, between Boston Road and White Plains Avenue, a quarter of a mile distant from the great highways of travel. It covers six acres of land, and is one of the most essential parts of the complex machinery for the maintenance of the zoological collection, the largest in the world. The superintendent of the Jungle Farm is Mr. Earnest Costain, who has a dozen or so of men to assist him in carrying on his work. The more than 1,000 different species of wild creatures in captivity in the Zoological Park have possibly a wider range of appetite than the throngs of people catered to by a great metropolitan hotel. The farm produces all the various favorite food-stuffs, such as corn, carrots, beets, cabbages, turnips, mangels, and other things to delight the appetite of the vegetarians among the jungle folk. The several breeding houses raise chickens, rabbits, guinea pigs, rats, mice, pigeons and squabs by the thousands for use of the carnivorous birds and big serpents. This great outdoor plant for the feeding of wild things from the ends of the earth was established because the open market could not be depended upon to furnish the large and varied list of foodstuffs required to satisfy the finicky tastes of these feathered, furry and scaled captive boarders from every clime. Their food tastes differ far more widely than those of a collection of the races of the earth. Aside from the necessity of keeping these valuable living specimens in perfect health, as far as that can be done by a carefully studied diet, the Zoological Park has found that it saves about fifty per cent in the cost of furnishing the supplies. Further than that, there is never a chance of shortage, as a great reserve stock of food of all sorts is kept constantly on hand. Every day a wagon takes over to the Zoological Park from the "Nursery," as the Jungle Farm is officially called, a big assorted load of fresh vegetables and fruit for the hungry boarders. Piled on top are the boxes containing the day's supply of chickens, guinea pigs, rats, mice, and other choice morsels for the meat eaters. The vultures, hawks and owls and other such sharp-beaked birds of prey know almost to the minute when their rations are due. Everything has to be absolutely hygienically clean. This is especially the case regarding the animal food furnished the carnivorous birds, animals, and reptiles. Infection of every sort is guarded against most carefully, for every specimen in the great park has a definite value. Some of the birds and beasts are priceless and have cost much money and the risk of many lives to secure. Owing largely to the care that is exercised in growing the food for the great collection of living creatures in the Zoological Park, and to the skill with which it is prepared and served, cases of illness among the "boarders" are very rare. The daily supply of vegetables and rations that comes from the farm is deposited with the cook, who weighs and arranges them in piles. The keepers then come with their push carts and load up their allotted rations and return to the various buildings to feed the animals. Here is a list of the number of livestock and quantities of vegetables that were raised last year and fed to the great army of housed animals and birds: 105 pigeons, 16 ducks, 2,600 chickens, 1,103 rabbits, 1,283 guineas, 762 mice, 2,735 rats, 2,000 worms, 22,958 eggs, 25 pounds honey, 44 pigs, 50 sparrows, 150 pounds grapes, 50 bushels chickweed, 60 quarts of strawberries, 20 tons mangels, 900 bushels beets, 30 barrels potatoes, 1,500 roots celery, 3,000 lettuce, 2,000 cabbage, 5,000 ears corn, 2 tons cornstalks, 40 bushels tomatoes, 29 bushels turnips, 50 quarts raspberries.

For most of the large carnivorous animals the meat is not cooked, but fed raw. For a change, several horses a week, after being pronounced fresh and healthy by the veterinarian, are also slaughtered and added to the meat courses. The food for the great collection of reptiles, giant pythons, cobras, boas and others, demands a special care. One of the largest and most showy of the inmates of the Reptile House is the huge regal python, nearly 24 feet long and weighing over 200 pounds. This mighty serpent possesses a color-pattern of a richness that rivals oriental tapestry, together with an iridescence which gleams in all the highlights of its folds. During the first few months of confinement very large specimens of this snake appear to suffer from the restraints of captivity. They steadily refuse food, and if energetic measures are not employed, they become emanciated, and gradually starve to death. Whenever the big python is found languishing and approaching toward a suicidal end, it is necessary to feed it by force, and thus either awaken or counteract its sluggish appetite. Young rabbits are killed and tied together with brown twine, the snake is held by the keepers in as straight a position as possible, when by means of a pole the meal is forced down its throat a distance of about six feet, and offering a novel and spectacular performance. Food thus administered usually changes the snake's demeanor toward captivity. With the meal once digested, there comes an appetite for food, which usually can be detected by the snake's actions, although for a time the reptile may lack sufficient courage to feed voluntarily. Careful attention on the part of the keeper is usually successful, and renders a repetition of compulsory feeding unnecessary. At present there is great relief to the keepers of the Reptile House as the giant python is feeding voluntarily on a 35-pound freshly killed pig. This meal is sufficient for several months. The king cobra is a cannibalistic species, in captivity usually refusing everything but snakes. Most of the other serpents, alligators, lizards, etc., feed upon young chicks, pigeons, rabbits, guinea pigs, rodents, all freshly killed, and devoured whole. Eggs are also swallowed entire.

Thousands of white rats are raised and fed to serpents and large birds of prey.



Very young chicks, a dainty meal for snakes, alligators, or lizards.



Rabbits bred on the Jungle Farm are fed to the big pythons and other snakes.

The Cleaning of Scientific Instruments Composed of Glass

By Albert B. Owens

IN making accurate estimations involving measuring certain fixed volumes of fluids, the perfect drainage of the fluid from the walls of tubes and flasks is a point that cannot be overlooked in exact measurements.

When the walls of a burette or flask show drops of fluid adhering after emptying them, it is a certain sign that they are not clean. This is due either to the presence of fatty, oily, or resin substances often too minute for the eye to detect.

In order to overcome this difficulty the flask or tube should be treated with the following solutions in this order:

To remove saponifiable oils (vegetable or animal origin):

1,000 cubic centimeters alcohol 95 per cent (denatured or straight ethyl).
100 cubic centimeters water.
100 grammes caustic potash.

This formula is made by dissolving the alkali in the water first and then mixing it with the alcohol. Allow this solution to act one hour, then return to stock bottle and wash instrument thoroughly with water.

To remove resinous matter such as varnish, shellac, etc.:

500 cubic centimeters acetone.
200 cubic centimeters ether.
100 cubic centimeters coal tar benzole.

This will prove very effective, in about 30 minutes, depending on the thickness of the film.

To remove deposits of carbon, left as residues from distillation in the bottom of test tubes, flasks, and retorts from oil and tar distillations:

1,000 cubic centimeters hot water.
200 grammes potassium bichromate.

Stir until the bichromate dissolves, then cool, and add gradually with constant stirring 900 cubic centimeters of cold, strong commercial sulphuric acid. To clean with this solution, half fill the flask to be cleaned with the bichromate mixture, and rapidly heat to boiling over a Bunsen flame. A rapid oxidation of all the carbonaceous matter occurs, the bichromate solution being reduced to a bright green color, and all of the carbon removed. This method of cleaning should be used after the other two methods fail to effect their object. There are of course other powerful cleaning agents like fuming sulphuric acid, but they are not common in most laboratories, and are expensive.

Forcing Strawberry Plants by Means of Ether Vapors

AMONG the several methods of forcing plants, hot-baths have been used with excellent results, but quicker and better results may be reached by submitting the plants to the vapors of ether. It is not very long since this treatment of the plants has been put in practice in hothouses, but so far it has always given excellent results.

Mr. G. Bultel, a French horticulturist, writes the *Revue Scientifique*, has utilized this method for forcing strawberry plants, and in each and every instance, the plants so treated have borne berries far in advance of those untreated.

His latest experience, made in the winter of 1911-1912, was with 600 plants, of which 300 were treated with ether vapor and 300 with hot baths. The 300 etherized plants were divided into two lots of 150 each. One lot was exposed to the vapors of ether in a closed house for forty-eight hours. The other was subjected to the same anesthetic for sixty hours. Notwithstanding the difference in length of treatment, the results were only slightly in favor of the plants subjected to the longer exposure.

The following table shows the results he obtained with both treated and untreated plants, showing the considerable difference between the two:

Number of plants.	Untreated.	Treated.
Blooming on January 8th, 1912	88	197
Blooming ended	January 29	January 16
First maturity	March 6	February 21
Last maturity	April 15	March 15

The exposure of the plants to the fumes of ether shows therefore a very decided improvement upon the earlier productiveness of the plants, and should be therefore of great advantage to the grower.

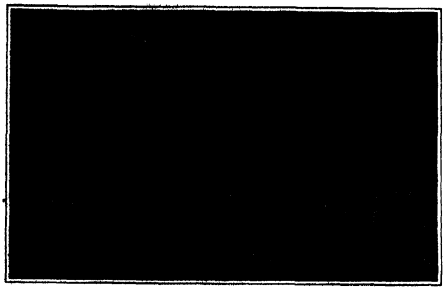
A Non-sinkable Mattress

IT is not a flood disaster that is depicted in the accompanying photograph; not an unfortunate victim washed out into the river, bed and all; but merely a striking demonstration of a new unsinkable mattress. The bed with a mattress arranged that so it is floating down the River Seine, Paris, in the presence of thousands gathered on the Pont Sully. A special buoyant fiber is used for the filling of the mattress. The inventor of this novel life preserver believes it essential for the equipment of every passenger-carrying vessel, so that in case of danger, one need merely pick up his own bed and use it as a raft. This novel demonstration was witnessed by the Assistant Secretary of Marine of France and a number of other officials.

A bed as a life raft.

A Razor That Chops the Beard

FOR the benefit of the man with heavy beard and tender skin a razor has been invented which cuts the beard by a chopping action. An electric motor is connected by a flexible shaft to the shaft of the safety razor. On the end of the razor shaft cylindrical cams are provided which change the rotating movement to a reciprocating one within the bladeholder. At the end of the holder this motion is again changed to one at right angles to the former, by means of a rocking arm and two prongs. Therefore the final motion of the blade is also a reciprocating one, causing the blade to act by means of blows against the hair. Many blows per second are administered, depending upon the revolutions per minute of the motor. The action of the blade is therefore not really one of merely cutting, but rather of severing by blows. The logical result is that it is not necessary to have the blades as sharp as it is now demanded. The chief advantage, however, is the rapidity with which a first-class shave can be accomplished, two to three minutes are sufficient. An application of soap is not necessary, wetting the skin will be sufficient. The sensation after the shave is very agreeable, resembling that of a mild massage. The motor may be connected by a plug with any lamp socket. It takes about 25 watts. The picture shows a combination set, the fan being intended for the use of the lady for drying her hair.



Vibrating razor that cuts the beard with a chopping action.

Laminated Gears

THE gear wheel has undergone but very slight changes in its production or design for many years past. Manufacturing methods are carried out upon either of two lines—casting, or cutting from solid blanks by machine. Both methods produce a very perfect wheel, and apparently are impossible of improvement.

Recently however an English inventor, Mr. A. E. Terry, a member of a well-known British engineering firm, has evolved an entirely new form of gear wheel, in the production of which also a new system of manufacture is employed. It is described as a laminated gear wheel. It is built up, but upon quite original lines. Instead of taking a solid blank of the required thickness, and machining the teeth, a number of thin disks of the desired metal are produced in an ordinary press, and the teeth on their peripheries are punched in accordance with requirements. These disks are then superimposed to the requisite thickness, and then clamped securely together by means of rivets, or bolts, producing a gear wheel as solid as that cut from a blank.

This is the elemental process and the disks can be fashioned from any suitable material, brass, mild steel, high tensile steel and so forth, at equal cost for labor. The rivet or bolt holes are punched simultaneously with the bore for the spindle, together with keyways or splineways, or they can be made to fit over a spider. The disks are then located on the tooth notching machine by the bore and the keyway, so that every other disk is identical as regards diameter of pitch circle, shape of teeth, and phase of the teeth relative to the keyway and bolt-holes. However, in building up the wheel each successive plate has its teeth phased one half tooth from its neighbor, the wheel thus comprising two distinct rows of teeth. This arrangement results in the halving of the virtual pitch and the doubling of the number of contacts.

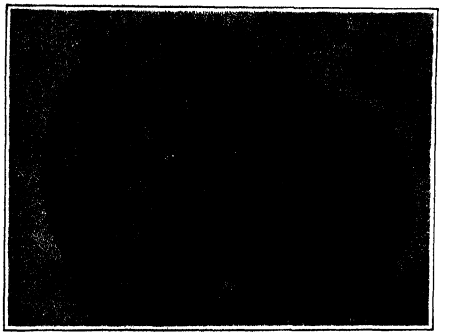
In the case of a large wheel the plates are mounted upon a spider, and bolted or riveted fast. The utilization of a spider allows a gear to be produced to any diameter, since the limiting factor is the spider and not the size of disks.

Should it be essential for the teeth of the laminated gears to be hardened there is no danger of distortion arising from the process, and subsequent grinding is not necessary. In hardening, the disks are packed on a mandrel to form a long pinion, with the teeth in line. Only the working faces of the teeth are hardened. The distortion of the disks is negligible, and when assembled, what little distortion may exist in regard to each individual plate, will not coincide with the rest, and hence it will be entirely neutralized.

The machines employed in cutting the disks are of standard design, while the dies, comprising a punch and die, to produce one tooth at a time, need neither an expenditure of considerable skill nor time in their preparation, and are not so costly as the cutters required for milling gears out of the solid. However, as the plate is in no way stressed while the operation of forming the teeth is taking place, there is nothing to disturb the location in any respect. Consequently, each disk is cut accurately.

In building up the wheel the disks are spaced apart by means of metal washers so as to leave a clearance for the teeth to pass without friction. From the searching and varied practical tests which have been made it has been ascertained that the laminated gear presents many advantages over that machined from the solid. It is practically as silent in running as raw-hide or silent chain drives because there is no hammering as each tooth comes into mesh, and because there is no "ring" in the wheel itself, this secondary sound being quite eliminated by the adoption of the lamination principle.

Another feature that cannot be overlooked is tooth fracture. In the laminated system this could only affect one or two plates, and would not throw the gear out of commission as is the case with a solid gear, while the defective disks may be readily replaced by dismantling the wheel.



Gear wheels made up of disks clamped together.

Disks used in laminated gears.

Libraries in an Indian State

THE very progressive native state of Baroda, in India, has no less than 275 public libraries connected with its Central *Library Department*, which was organized by Mr. W. A. Borden of New Haven, Connecticut. These contain about 156,000 books, and within the last three years the number of readers is said to have increased nearly 360 per cent. The department has also a system of traveling libraries, which remain at each village three months, after which fresh books are furnished; besides which each village gets a grant for the purchase of books for local libraries up to $100 a year, provided an equal amount is subscribed by the inhabitants. The central library, in the city of Baroda, will shortly open a special department for women readers. A visual instruction department to educate people who cannot read, and to promote knowledge of the outside world by means of stereoscopes and cinematographs, is also in operation. The Central Library Department of Baroda issues the only periodical in India devoted exclusively to library topics. The literary development of Baroda is further indicated by the fact that in the year 1910 there were about 200 books published by natives in this state.

A New Route to the Belgian Kongo

AN event of great economic and geographical importance will be the opening, early in 1914, of the extension of the present railway across German East Africa to Lake Tanganyika. The eastern terminus is Dar-es-Salam, on the Indian Ocean. At the lake end the Germans are building the port of Kigoma-Ujiji, from which a line of steamers will run to Albertville, in the Belgian Kongo, where a port is now being constructed under the supervision of Capt. Mauritzen, hydrographer of the Danish Navy. Albertville is the terminus of the Great Lakes Railway, which in a few years will connect with the other railways of the Belgian Kongo and with steamers on the Kongo River.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Pertaining to Apparel.

HOLDER.—J. MACDONALD, 218 W. 14th St., New York, N. Y. The invention refers to wardrobe fixtures, and provides a holder for neckties, buttons, scarf pins, coats, trousers, and other articles of wearing apparel and arranged for convenient attachment to a wall, wardrobe or the like, and for protecting the supported articles against dust.

Pertaining to Aviation.

AEROPLANE.—J. G. HANNA, 1215 S. Franklin St., Muncie, Ind. The purpose here is to provide a device for sustaining weight, and moving the same through air by atmospheric reaction on a curved surface or surfaces impelled either by a force of gravity or by mechanical power, and for insuring stability, great strength, and power of absolute control at all times.

Electrical Devices.

AUTOMATIC FUSE RESETTER.—J. B. ELKIN, 1802 Main St., Columbia, S. C. The main purpose here is to provide a device for use in connection with telegraph or telephone circuits for resetting fuses which have been burned out by lightning. A further object is to provide for automatically resetting any number of fuses, thereby obviating the necessity of setting the device after each operation, preparatory to the next.

Of Interest to Farmers.

ROTARY PLOW.—M. E. PLATFORD, Wakelee, Mich. This improvement has reference to plows, the more particular purpose being the provision of a so called "rotary plow" having spiral cutting blades so formed and fitted as to be specially adaptable for use in a motor plow. It can be readily assembled or taken apart for transportation or storage.

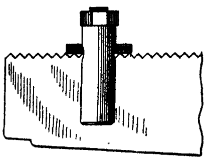
Of General Interest.

LIFE SAVING SUIT.—J. P. PARK, Beloit, Kan. Mr. Park's invention has reference to a suit more particularly designed to be worn by marine travelers in case of shipwreck. The suit is made from a suitable waterproof material and may be provided with a life preserver, or be adapted to receive an ordinary life preserver. The body of the suit is provided with legs and arms as shown in the accompanying illustration, the arms, if desired, having integral mitts.

LIFE SAVING SUIT.

Hardware and Tools.

SAW JOINTER. F. M. BARNARD, Milford, Iowa. This invention is an improvement in saw jointers which is always ready for use and which may be used on any type of saw. The device is small and compact, and with the file removed may be easily carried in the pocket. With the file in place, it is firmly clamped so that it cannot be displaced by its engagement with the teeth and when any part of the file becomes worn, the file may be shifted longitudinally or turned until it is completely worn out.



SAW JOINTER

Heating and Lighting.

DAMPER CONTROLLING DEVICE.—F. A. KATELEY, 11 Wallace Ave., Mount Vernon, N. Y. The invention provides a device arranged to actuate the damper according to the pressure of the steam generated in the steam-heating apparatus, to prevent spilling of water in case of excess pressure in the apparatus, or in case a siphoning action takes place on forming a vacuum in the steam compartment of the steam heating apparatus.

GRATE BAR.—G. S. SERGEANT, Greensboro, N. C. This invention is an improvement particularly in grate bars made in sections held together end to end, and relates to means for supporting the sectional grate bar at the middle portion thereof. Means provide for employing the longest grate bars ever required without increasing the weight per linear inch, thus making the cost per linear inch no greater for long bars than for shorter lengths. Any style of grate surface and of vent can be employed to suit the various kinds of fuel which it may be desired to use.

GRATE BAR.

Household Utilities.

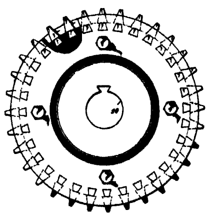
ICE CREAM FREEZER.—E. THOMPSON, 202 E. 46th St., New York, N. Y. In this device a circulating brine or similar freezing fluid is used as the freezing medium. The invention provides a freezer arranged to provide a large refrigerating surface, to avoid dormant nonfreezing surfaces, thus insuring a more rapid freezing and preventing deterioration in the texture and quality of the ice cream.

Machines and Mechanical Devices.

CLUTCH.—J. J. GILMARTIN, Guild, Tenn. Mr. Gilmartin's invention is an improvement in clutches, and has for its purpose to provide a clutch, especially adapted for splicing flexible members of metal, as for instance cables, ropes, and the like, wherein mechanism is provided for rigidly holding the ends of the cable together in the form of a square or reefing knot. With the use of the improved block there is no weakening of the cable at the knot.

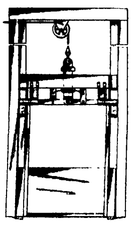
CLUTCH FOR CABLES, ROPES, ETC.

GEAR WHEEL.—A. S. FINCH, 70 Henry St., Passaic, N. J. This invention provides a gear wheel having gear teeth dove tailed removably in the periphery of the body of the wheel with base extensions which are adapted to engage in openings in plates applied to the sides of the body of the wheel, whereby the said plates hold the gear teeth against lateral displacement and also afford additional securing and strengthening means for the teeth.



GEAR WHEEL.

SAFETY DEVICE FOR ELEVATORS.—M. C. HUTCHINGS, Bozeman, Mont. This invention provides a device for use with elevators, mine hoists and the like, which becomes operative instantly if the cable of the elevator becomes broken or relaxed, and which then serves to bring the elevator car to a stop before it can travel any material distance, which will in no manner interfere with the normal operation of the elevator, that cannot be inadvertently rendered operative when not needed, and which can be instantly automatically released after the grips have become operative.



SAFETY DEVICE FOR ELEVATORS

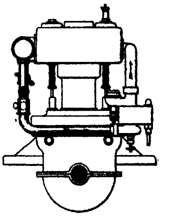
COAL CONVEYER.—O. S. BARNES, 403 Albemarle Road, Brooklyn, N. Y. This conveyer for handling coal or other articles of merchandise in bulk includes an endless series of buckets and adapted for free operation in any position of adjustment with respect to movement laterally around a vertical axis or with respect to vertical adjustment parallel to said axis.

ENVELOP OPENER.—W. N. BUSKIRK, Roanoke Ave., Riverhead, N. Y. In this patent the invention has reference to stationary articles and particularly to devices for opening envelops or the like by means of a cutter adapted to cut a slit closely parallel to one of the lateral edges or ends of the envelop.

STOP MOTION.—F. AINSWORTH, 877a Gates Ave., Brooklyn, N. Y. This stop motion is more especially designed for use on sewing machines and the like, and arranged to automatically stop the machine whenever the needle thread or the shuttle thread breaks or runs out, and to permit of conveniently applying the stop motion to sewing machines as now constructed.

Prime Movers and Their Accessories.

STARTER FOR INTERNAL COMBUSTION ENGINES.—S. G. BERRY, Tyndall, S. D. The invention refers to a starting construction for internal combustion engines, and the purpose is to provide a starter comprising a pipe connected to supply air warmed by the exhaust of the engine to the carbureter, and having means therein for vaporizing a sufficient quantity of gasoline independently of the carbureter in order to facilitate the starting of the engine in very cold weather.



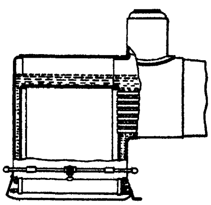
STARTER FOR INTERNAL COMBUSTION ENGINES.

GASKET AND RETAINER THEREFOR.—A. E. HART, 4 Fourth St., New Brighton, S. I., N. Y., N. Y. The intention here is to provide a structure designed to hold a gasket in place in an automatic air coupler under high pressure, the same co-acting with a high pressure air pipe and with resilient means for holding the coupler in a predetermined position for maintaining the gaskets of co-acting coupler heads in contact.

INTERNAL COMBUSTION ENGINE.—J. KERNER, Avenue d'Argenteul 266 Asneres, Paris, France. This invention relates more particularly to an engine of the two-cycle type which comprises a cylinder, a crank case closed with respect to the cylinder and a piston in the cylinder and having a piston rod intermittently effecting communication between the cylinder and the crank case.

Railways and Their Accessories.

AUTOMATIC MUD DRUM FOR BOILERS.—A. F. SHREVE, Hoisington, Kan. This invention relates to mud drums for boilers, the particular purpose being to provide a mud drum so constructed and arranged as to be automatic in the sense that it operates continuously and positively in the removal of mud and sediment from the boiler. The invention further relates to provision of means for removing the mud and sediment from the mud drum.



AUTOMATIC MUD DRUM FOR BOILERS.

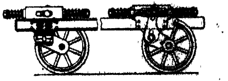
STORMPROOF CAR DOOR.—G. M. KIRBY, Aurora, Mo. The main object in this instance is to provide a door for a railway car or other inclosure that will be simple and practical in its construction, and so mounted as to make a perfectly stormproof covering for the doorway with which the same is to be used.

Pertaining to Recreation.

BATHING BOAT.—C. M. JOHNSON, care of A. Johns, 60 Wall St., New York, N. Y. This inventor provides a boat having a supporting section submergible at will, to form an inclosed bathing area arranged to prevent accident to the bather; provides a pleasure boat having a deck through [illegible] passes, and means for, [illegible] portion of the deck for [illegible] boat with a motor-actuated [illegible] and provides means for [illegible].

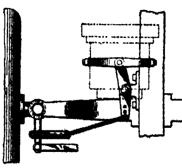
Pertaining to Vehicles.

VEHICLE SPRING SUSPENSION.—[illegible] BUSHEY, 180 Badger Ave., [illegible] This invention relates to an improved spring suspension which absorbs all shocks lengthwise and sidewise to the frame, and does away with the necessity of using pneumatic tires on motor cars. A mechanism is devised in which the vertical movement of the axle is yieldingly resisted on the frame, both when the frame and axle move toward each other and when away from each other, and the invention also provides a means for making the attachment between the frame and the axle more flexible by giving each individual wheel, or rather its ends of the axis, a limited movement without affecting the other end of the axle or the other wheel on the same end of the frame. Shock absorbing devices of this kind have been employed, but the present invention relates to the flexible attachment of each end of the axle to the body of the vehicle or the frame. In prior devices the shock absorbers in instances have been connected by transverse connections. In this invention each end of each axle is supported in a way that permits that end of the axle and the frame to have a relative movement without affecting the other end of the axle or the other axle.



VEHICLE SPRING SUSPENSION.

DIRIGIBLE HEADLIGHT.—A. C. HENDRY, care of Walter Scott, Davenport, N. Y. This invention relates to apparatus for connecting a headlight or headlights to a moving vehicle, having particular reference, however, to automobile headlights whereby at least one of the lights will be caused automatically to be steered in unison with the steering apparatus of the vehicle so as to illuminate the roadway in the direction in which the vehicle is to be operated at the turn.



DIRIGIBLE HEADLIGHT FOR AUTOMOBILES.

AUTOMOBILE TOP.—CARL V. BEEBE, Mount Gilead, Ohio. This invention relates to automobile tops comprising a canopy or curtain, and means for securing the curtain in position or for storing it when not required for use. The top can be placed in position with convenience and dispatch, and quickly and conveniently lowered and stored into small compass when not in use. The auto-top can be raised by an occupant without leaving the car and one can raise and lower it without assistance. The invention may also be employed in connection with other vehicles.

VEHICLE MOUNTING.—A. A. PRATT, 54 Wall St., New York, N. Y. The invention provides a mounting or suspension which is exceedingly sensitive and arranged to take up all jars and jolts incident to the vehicles traveling over rough roads, obstructions and the like, to insure easy and comfortable riding without requiring the use of pneumatic or similar tires, thus reducing tire expense to a minimum and eliminating danger and delay caused by bursting tires and the like.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

PATENTS

TRADE MARKS DESIGNS COPYRIGHTS &c.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their Inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty-five years ago.

All patents secured through us are described without cost to patentee in the Scientific American.

MUNN & CO., 361 Broadway, New York
Branch Office 625 F St., Washington, D.C.

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance.

AGENTS WANTED

AGENTS make big money selling our new gold letters for office windows, store fronts and glass signs. Any one can put them on. Write for free sample and full particulars. Metallic Sign Letter Company, 438 N. Clark Street, Chicago.

AGENTS—You can't afford to accept ordinary propositions while agency for Guaranteed Aluminum Cooking Utensils is open. Answer quick. Protected Terr. Am. Aluminum Mfg. Co. Box 8A, Lemont, Ill.

GENUINE ARCHEOLOGICAL SPECIMENS

A GENUINE Babylonian tablet with cuneiform writing as supplied to Yale University and other institutions will be sent on receipt of $2. Money back if not genuine or if it does not please you. E. D. [illegible], 90 Beaver Street, New York City.

INSTRUCTION

LEARN TO WRITE ADVERTISEMENTS.—Earn $25 to $100 weekly. We can positively show you by mail how to increase your salary. Prospectus free. Page-Davis Co., Dept. 89, Chicago, Ill.

PATENTS FOR SALE

PATENT adjustable stilts—will create a craze equal to roller skates or the bicycle. A million boys will sell their pants if necessary to get a pair of stilts on which the footholds can be raised or lowered. There's thousands in them and millions after them. I offer the right for sale. L. L. Steinbach, Homer, N.Y.

MISCELLANEOUS

WE ANALYZE and test everything. Have you anything you want tested? We furnish formulas and make up compounds at lowest prices. Laboratories 731 East 161st Street, New York.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. *In every case it is necessary to give the number of the inquiry.* Where manufacturers do not respond promptly the inquiry may be repeated.

Munn & Co., Inc.

Inquiry No. 9340. Wanted the name and address of manufacturers of knock-down barrels, staves, hoops and heads which may readily be assembled.

Inquiry No. 9341. Wanted, mail order article. A man with long experience in the newspaper and advertising field desires to get in touch with the inventor or manufacturer of some quick-selling article, with the idea of inaugurating a Mail Order business to mutual profit.

Inquiry No. 9342. Wanted, a machine to cut No. 18 wire in 2½ inch lengths and sharpen both ends similar to tack points. One operation preferred.

Inquiry No. 9343. Wanted the name and address of manufacturers of machines for grinding the peel of oranges and grapefruit.

Inquiry No. 9344. Wanted name and address of manufacturers of patent articles of merit suitable for mail order distribution.

Inquiry No. 9345. Wanted name and address of manufacturers of Oxy-Acetylene Cutting and Welding Torch, also an easy opening can suitable for shoe polish.

Inquiry No. 9346. Wanted the name and address of parties manufacturing tobacco stripping machines, and other machines pertaining to cigar manufacturing and cigar banding machines.

Inquiry No. 9347. Wanted the name and address of an industrial school where shoemaking is taught in all its branches.

Inquiry No. 9348. Wanted the name and address of manufacturers having useful household necessities, with a view to obtaining exclusive territory for a house to house canvass.

Inquiry No. 9349. Wanted the names and addresses of the makers of machinery for making Malt Tonic, also a machine for making grease, and machines for applying plaster (Cement Gun).

Notes for Inventors

A New Product in the Form of Butter.—Joseph Moses Ward Kimball, of East Orange, N. J., has secured a patent, No. 1,072,369, for manufactured and packed butter. This is defined as a butter that has been in a state of frigidity from the time it has been made to the time it reaches the consumer. By keeping the temperature below the freezing point proliferation of the germs in the butter is prevented. Still, the germs in the butter are in a state of vital inhibition and the butter is substantially free from objectionable flavors and odors due to the vital activity of germs.

Protecting the Baby's Head.—Belle G. Fitch, of Philadelphia, Pa., has patented a head protector for babies which has a single pneumatic tube of soft expansible material which fits around the head horizontally and has pairs of converging tubes which extend upwardly from the opposite sides of the horizontal tubes, with all of the tubes in communication with each other. The patent is numbered 1,072,321.

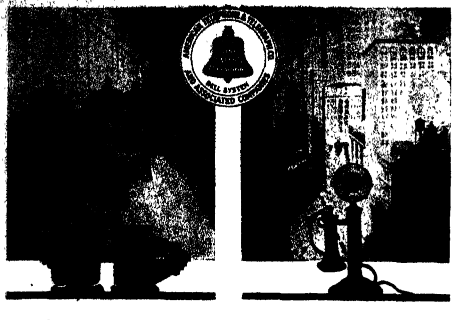
Toy Suggestions.—Two forms of toys appear to be more or less neglected at the present time. These are the airship toys which are projected and sail through the air, and the toy doll and animal figures carried on the hand and manipulated by the movements of the fingers. The airship toys present a field for improvement in the projecting devices and in the stabilizers and direction controlling features while in flight. Possibly the toys could be made to return boomerang fashion. The doll and animal figure toys present opportunities in the way of novelties in the design of the toy as well as in devices for facilitating manipulation to more nearly simulate the lifelike movements.

A Geographical Amusement Device.—In patent No. 1,070,546 to Hanson Robinson of Detroit, Mich., as assignee of John F. Sherlock and Henry Spengler of New York city, is presented a toy having a hollow globe with geographical markings and inclosing a magnet loosely mounted in the globe and counter-weights to preserve an upright position, and operates a keeper in the form of a ship on the outside of the globe so the ship by the turning of the globe can be made to appear to travel along any desired route.

A Gastronomic Clock.—A curious "gastronomic clock" is said to have been made in the old times by an ingenious Frenchman for telling the time in the dark. He installed a large flat clock dial beside the bed on which the hours each had a small cavity. In each one he placed a different spice, for instance, the figure 12 held quiqe and the figure 6 cloves, and so on. To find the time, he followed the short hand with the finger and then tasted the contents of the cavity opposite, then he did the same for the long hand, and had he pasted pepper and nutmeg, for instance, he knew that the hour was half-past three.

An Invention of the Future.—Thomas A. Edison is reported as saying that an improvement to be expected in the future is along the line of permitting the re-use of paper for newspaper purposes, by removing the printer's ink so the paper can be used a second time. Economy would be doubly served by such an invention as it would not only permit the re-use of the paper but might also lead to a recovery at least in part of the ink or ink particles for subsequent use if the ink should be removed from the paper.

Base Signal for Baseball Fields.—With the kindest of motives and in behalf of the poor umpire of a baseball game, Stephen H. Wills has invented a base for a baseball field which will give an alarm or signal when a runner reaches or touches it, thus avoiding the dispute which now commonly takes place between the runner and the umpire and the other members of the team as to whether or not the runner reached first base before the baseman caught the ball. This is accomplished by having the baseplate or bag hinged and raised at one edge by a spring. When the runner touches the base it is depressed, making an electrical contact which sounds the alarm or makes the signal. The number of the patent is 1,066,773.



The Energizer of Business

IN a metropolitan power-house there must be generators large enough to furnish millions of lights and provide electrical current for thousands of cars and factories.

Each monster machine with the power of tens of thousands of horses is energized by an unobtrusive little dynamo, which is technically known as an "exciter."

This exciter by its electric impulse through all the coils of the generator brings the whole mechanism into life and activity.

A similar service is performed for the great agencies of business and industry by the telephones of the Bell System. They carry the currents of communication everywhere to energize our intricate social and business mechanism.

United for universal service, Bell Telephones give maximum efficiency to the big generators of production and commerce.

NEW BOOKS, ETC.

Engineering as a Profession. Scope, Training and Opportunities for Advancement. By A. P. M. Fleming, M.I.E.E., and R. W. Bailey, Wh. Sc., Principal of the Technical Institute, Crewe. London: John Long, Limited, 1913. 8vo.; 288 pp. Price, 2s. 6d. net.

Knowing the proud position attained by the profession of engineering under the complex physical conditions of modern civilization, and having heard of the rich rewards many of its members have won, parents are too apt to overlook the prime necessaries of individual leaning and talent, and the arduous, skillfully-directed years of labor and learning that are indispensable to even a moderate success. The authors of this friendly guide are well qualified to disperse the prevailing ignorance that, failing to recognize what constitutes a suitable course of training, or to grasp the conditions surrounding engineering employment, practically invites ignominious failure in the chosen profession. The work in hand broadly reviews the various branches of this profession, tells exactly how the necessary training may be acquired and at what cost, with a special chapter devoted to the acquirement of such knowledge at a minimum expenditure, and discusses appointments in civil, mechanical, and electrical fields, with particular reference, of course, to Great Britain and her colonies. Under "Foreign Methods" is sketched the training of engineers by the German and American systems.

Wireless Telegraphy. By C. L. Fortesque, M.A. New York: G. P. Putnam's Sons, 1913. 16mo.; 143 pp.; illustrated. Price, 40 cents net.

This text is addressed to the reader having some general scientific knowledge, and deals with an important subject in a manner that is simple yet adequate to the purpose. The electrical phenomena involved are explained as far as possible by mechanical analogy. The principles of these phenomena are then applied to wireless apparatus, and the latter half of the little volume is given over to a survey of the most modern uses of the art. Marconi and Telefunken apparatus are clearly shown in illustrations, and the arrangement and operation of the instruments is thoroughly explained.

Addresses and Papers on Life Insurance and Other Subjects. By John F. Dryden. Newark, N. J.: The Prudential Insurance Company of America, 1909. 8vo.; 330 pp.

These papers deal with the inception, progress, and results of industrial and ordinary life insurance, and will prove of the highest value to those interested in the subject. The author was United States Senator from New Jersey from 1902 to 1907, and his senatorial utterances on the American type of Isthmian canal are included in the volume.

Pearls and Pearling. By Herbert H. Vertrees. New York: Fur News Publishing Company, 1913. 12mo.; 203 pp.; illustrated.

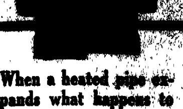
Few people realize that the United States has a well-established pearl industry—that, for example, in 1910 there were 2,600 pearling boats on the Illinois River, and that this is but one of many rivers that yield the pearl mussel. Mr. Vertrees' little book is a clear exposition of the methods and paraphernalia of sweet-water pearl hunting, and fills a gap in the literature of the subject. It also enters into the history and origin of the pearl, describes the life and habits of the mussel, and adds a description of the "cripple" in which the fine pearl is oftenest found. The values and uses of the various shells are listed, the reader is instructed in the art of prospecting, and the crow-foot dredging outfit and its manipulation is thoroughly described. There is, too, a study of the influence of local conditions upon the color of shells and pearls, and the luster of the pearl is explained. The manual is quite up to date in information and in methods, and not only affords the prospective pearl hunter invaluable information, but also interests the general reader in no small degree.

Seehafenbau. Von F. W. Otto Schulze, Professor des Wasserbaues an der Technischen Hochschule in Danzig. Band II. Ausbau der Seehäfen. Berlin: Wilhelm Ernst & Sohn, 1913. 8vo.; 523 pp.; mit 574 textabbildungen bestehend aus 957 Bildstocken. Preis des Werkes, Geh. 24.—M. Geb. 25.—M.

We mentioned favorably the first volume of Prof. Schulze's work on its appearance some time ago. Vol. II is an extension of the thorough studies of the first volume, carefully expounding harbor construction as exemplified in the harbors of the world. The various features of construction are progressively considered—breakwaters, moles, bulkheads, seawalls, wharves, piers, towers and structures pertaining to the loading and unloading of vessels, and the various types of crane, including the floating crane. There is a section also on excavators and dredges. By means of unstinted sketches every detail of plan and structure is distinctly shown. There is an exhaustive index covering both volumes.

The Physiography of the Rio Grande Valley, New Mexico, in Relation to Pueblo Culture. By Edgar Lee Hewett, Junius Henderson, and Wilfred William Robbins. Washington: Government Printing Office, 1913. 8vo.; 77 pp.; with maps and illustrations.

This bulletin is the result of two years' coöperative work by the School of American Archæology and the Bureau of American Ethnology, and consists of three papers on the Rio Grande Valley, its geology and topography, its climate and the evidence of [illegible]



When a heated pipe expands what happens to the unions on that pipe?

If the unions are *malleable iron*, the expanding pipe *stretches* them because malleable iron has a *lower* coefficient of expansion under heat than does the wrought iron or steel pipe. Then when the pipe cools and contracts it shrinks away from the stretched union and leaves a leak.

THE MARK Cold Drawn STEEL UNION

is the happy solution.

Because the *wrought steel* of the union has the same coefficient of expansion and contraction as the wrought pipe—and the Mark Cold Drawn Steel Union expands and contracts in perfect harmony with the pipe.

CONSEQUENCE: No leaks, and a lot of expense and labor saved.

This is only one of a long list of exclusive features of this new and better pipe union.

[illegible] Trained Men—IX

[illegible] in Iron and Steel Making

By S. T. Wellman

[illegible] Wellman, the author of the following article, has had a large part in the development of the iron and steel industry from small proportions just after the civil war to the enormous production of to-day. He is the inventor of a tilting open hearth furnace and of the charging machine which made the open hearth furnace [illegible]. Mr. Wellman has been general superintendent and engineer of the Otis Iron and Steel Company and president of the Wellman Seaver Morgan Company. He is past president of the American Society of Mechanical Engineers and of the Cleveland Engineering Society. He is a member of the American Institute of Mining Engineers, the American Iron and Steel Institute and of the British Iron and Steel Institute.—Editor.]

Is the profession of "Iron and Steel Making" a good one to follow? This is a question that is asked many times by young men who are trying to make up their minds as to their life's work.

The answer will depend very largely upon the man. Many would not like the business at all, and some, as I have seen them do, would turn and leave at the first sight of what the work and conditions are, saying: "None of that for me."

One young man that I remember many years ago, at his first sight of a Bessemer converter timing up, sending as it always does a shower of fire across the building, turned and fled headlong and never stepped inside the works again.

To me the iron business is the most fascinating in the world. All of the processes are interesting. New problems, mechanical and metallurgical, are constantly coming up to be solved.

There is plenty of room in the iron business for workers, but none for drones. The young man who adopts it for his life's work must have in the first place a good physique; he must be strong and healthy in mind and body, not afraid of work or dirty hands or rough clothes. He must expect at times to make long hours, when he is learning the business, and at times he will have a great deal of night work.

A college or technical school education is not absolutely necessary, but it is very desirable. The young man who starts in the business without such an education, must make up for the lack of it by a lot of self education at home, if he wishes ever to reach the top of the ladder. That it is possible to do this is shown by the careers of many of the brightest and most successful men in the business. Night and correspondence schools are open to the poor working boy who has the ambition to rise, and who is bound to learn all that is worth learning in his chosen profession. The very fact that he has to work hard in the face of all kinds of difficulties to learn what he is after, is the best kind of a beginning of a training for what is to come.

Many times, when asking professors at technical schools and colleges to send me graduates for different positions, I said to them: "Everything else being equal, I would rather have a poor boy who has worked his way through college than a rich man's son who doesn't know the value of a dollar, and whose chief reason for being at college is to have a good time."

The common opinion is that the poor boy is the one who is handicapped in making the race for real success in life. I am not sure but that this is wrong, and that it is very possible that the rich man's son, surrounded by every luxury, who lives in a beautiful home, with a doting mother watching over him, who never learns or knows the value of money, is the one to be pitied, and is really the boy who is handicapped.

The best assistant that I ever had was a young man who was the son of a barber. He graduated at the high school, after which he went to work in the office of an iron works of his native town. In a year or two he had saved five hundred dollars. With this and the addition of one thousand dollars which his employer loaned him, he went to Germany, where he stayed four years. This amount of money paid all his expenses. Of course, this was possible only by the exercise of the most rigid economy. He entered the University of Berlin, where he graduated, taking the highest honors that any American had taken up to that time. He spent all of [illegible] details of the business practically, but making many acquaintances that were valuable to him in after life. It is needless to say that he succeeded in everything that he took hold of. A man who goes at things in the enthusiastic way of this young man, is always sure to succeed.

A most excellent way for any young man to do who is trying to make up his mind whether he wants to learn and follow the iron business, is to spend one of his vacations, or a portion of it at least, in some steel works or rolling mill.

After this experience, if he makes up his mind that he wants to learn the business and follow it up as a profession, he can go back to school and go to work in earnest to learn any and everything that will help him in his chosen field of work.

I believe it is a most excellent plan for a student to spend at least a month of each year out of his vacation in some works, seeing the thoroughly practical side of the business. Every time after doing this, he will go back to college with fresh courage and a better understanding of what he needs to learn, and he will see how necessary the purely theoretical part of his education is.

Of course, no matter what profession a young man follows, one of the great advantages of a course at college is the associations and the acquaintances he makes there, which will always be pleasant and useful to him in after life.

When he has finished at college and obtained his coveted degree, he must not think that he is fitted to take charge of any works, or even a department of it. If he has sense, he will know that he is only learning the theory of things, but the hard practical part he has yet to learn.

A man who expects to be a leader in any business should know every detail. He should be able to take any workman's place for a short time. I don't mean to say that he should work at every branch of the trade long enough to become a first-class workman, but he should work at it long enough to get a thorough, practical understanding of it. If he does not do this and does come to a position of responsibility, not understanding the details in a practical way, the workmen will very soon find it out and they will be sure to take advantage of his ignorance.

Of course, if a young man goes into the iron business and expects to earn a living with his hands and muscles only, and to be merely a workman, skilled or unskilled, book knowledge will not help him very much. He might as well stop with a common school education. But if he wants to make his brains and not his hands do the work, he must get all the help possible from the best that books can teach. Of course the scientific school is the best place to do this.

Workmen who have a superintendent under whom they have learned their trade are more easily managed than if they had brought their trade with them, and its details are in any part a secret from the management. If they know that the superintendent knows just as much about it as they do themselves, they will know that, having taught them, he can teach others. Strikes are not likely to happen where the management is in such hands.

To my mind, the business of the ironmaster is the most interesting of any of the great professions. Every part of the work is full of the most interesting and picturesque detail, from the taking of the crude material from its bed in Mother Earth to the turning out of the finished iron and steel, and nowhere is it carried on in such magnificent scale as in this country in which we live.

Mitchell Sixes

Products of Long Experience

This company has been building popular priced sixes longer than any other concern in this country. Hence the sixes we offer are the product of many years of experience, and in no sense experiments.

The *Mitchell Little Six* which was known as the "Baby Six" in 1912, is, in our opinion, the profoundly logical investment in the automobile market. It is not only the sensible compromise between big and little power and passenger capacity, but it has everything that any high-priced car can offer you.

It has quality that insures long life. It has the style of beauty that the exacting mind demands. It has as much speed and power as any person can desire. It will hold its place in any company and look classy and work perfectly for several years to come. Its equipment is complete and details thereof sterling in character. The price, $1,895, brings this smart car to you ready for instant use. There is nothing left for you to buy—no extras—no appurtenances.

The *Mitchell Big Six* is the biggest and best car at the price that has ever been produced. It is built along the same lines as the Little Six save that it has 144-inch wheel base, somewhat larger tires, greater passenger capacity. Yet the quality of the two are identical. The equipment is precisely the same—the outward beauty similar. For a big family car the Big Six has no equal in America and there is nothing as good for less than $3,500 or $4,000. The price of the Mitchell Big Six is only $2,350.

The *Mitchell Four* is intended for those who feel that they cannot afford either of the Sixes. It is the only four-cylinder car we make. We build it to meet the demand of those persons who still like a four-cylinder car of class at a popular price. It has the same equipment as the other two cars and sells for $1,595. We want you to look this car over minutely and then ask yourself if there is a four-cylinder car at anywhere near the price that can compare with this one in any detail.

Here is the Equipment for all the Mitchell Models Which is Included in the Price as Given

Electric self-starter and generator—electric lights—electric horn—electric magnetic exploring lamp—mohair top and dust cover—Tungsten valves—Jiffy quick-action side curtains—quick-action two-piece rain vision wind-shield—demountable rims with one extra—Speedometer—double extra tire carrier—Bair bow holders—license plate bracket—pump, jack and complete set of first-class tools.

Specifications of the Three Great Mitchell Models:

Mitchell Little Six—fifty horse-power—112-inch wheel base—36 x 4½ in tires—two and five-passenger capacity	$1,895
Mitchell Big Six sixty horse-power 144-inch wheel base—37 x 5 in tires—seven-passenger capacity	$2,350
Mitchell Four—forty horse-power 120-inch wheel base four cylinders—36 x 4½ in. tires—two and five-passenger capacity	$1,595

Eighty Years of Faithful Service to the American Public

JUST PUBLISHED

Wireless Telegraphy and Telephony

SIMPLY EXPLAINED

70 pages, 156 Illustrations. By ALFRED P. MORGAN. Price $1.00 Postpaid.

The simplest, latest and most comprehensive popular work published on wireless, for the wireless operator, amateur or professional.

This is undoubtedly one of the most comprehensive treatises on the subject, and a close study of its pages will enable one to master all the details of the wireless transmission of messages. The author has filled a long-felt want and has succeeded in furnishing a lucid, comprehensible explanation in simple language of the theory and practice of wireless telegraphy and telephony.

The book treats the subject from an entirely new standpoint. It is well illustrated by over one hundred and fifty interesting photographs and drawings. All diagrams have been made in perspective, showing the instruments as they actually appear in practice. The drawings are carefully keyed and labeled. Many of the photographs are accompanied by phantom drawings which reveal the name and purpose of each part.

A book the wireless experimenter cannot afford to be without. It enables one to design and construct apparatus. Also valuable to the layman.

MUNN & COMPANY, Inc. 361 Broadway, New York City

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12910) P. R. B. asks: Please inform me if I can get through you any literature descriptive of the experiments by which the velocity of sound in water was determined. A. The velocity of sound through water was measured in 1826, by Colladon and Sturm in the water of Lake Geneva. A bell under water was struck, and at the same instant some gunpowder was flashed in the air above. At a station more than 13 kilometers (8 miles) away a sort of big ear-trumpet, closed by a membrane, was placed with the membrane under water, the tube rising above the surface. An observer with his ear at the tube noted the interval between the arrival of the flash and the sound. The velocity deduced at 8.1 deg. Cent. was 1435 meters per second, agreeing very closely with the calculated value. This account is taken from the Encyclopedia Britannica, eleventh edition, vol. 25, page 443C.

(12911) C. C. asks: Can you give me a simple and comparatively inexpensive formula that will remove fat or grease from enamel and porcelain "plates"? A. The best solvent for fat or grease is potash. This changes the fat into soap and it is then easily removed with water. Any acid which would cut the grease would be so strong that it would also cut the skin of the person working with it.

(12912) F. P. asks: How is it possible for a wind instrument to be "flatted" or blown out of tune? A. The changing of the tone in pitch by overblowing, as it is called, is common to all wind instruments. It is treated in Barton's "Sound," under the several instruments. We send the book for $3.25 postpaid. With instruments where the lips form the reed whose vibrations produce the tone, the size of the tube and the temperature of the air have an important effect upon the pitch of the tone. On the cornet it is said that the player can force the note a quarter tone flatter or sharper than its normal pitch. Barton, page 449.

(12913) J. M. L. asks: Can you furnish me with a description or give any information pertaining to apparatus for producing nitric acid from atmospheric air, from Bradley and Lovejoy, Birkeland-Eyde? It is mentioned in the SCIENTIFIC AMERICAN of September 6th. A. We have published several papers on the modes of producing nitric acid by the electric arc. You will find them in our SUPPLEMENT Nos. 1640, 1641, 1642, 1643, 1644, a series, also 1667, 1668, 1691, 1692, 1748, 1767, and 1784, price ten cents each. These papers will give you a complete review of the subject.

(12914) H. W. R. asks: I would be glad to know your authority for the statement that the Roentgen rays have the precise wave length of 0.01 micron. A. The authority for the statement of a wave length for Roentgen rays is the reports upon the diffraction and interference measurements of these rays, which have appeared in the scientific periodicals for several years past. If you are a member of the American Physical Society, you will have a file of the Science Abstracts, Section A, in which you will find the abstracts of these papers. We would refer you to the following: June 30th, 1913, vol 16, part 6, Abstract 994, July 28th, 1913, vol. 16, part 7, Abstract 1,153; October 27th, 1913, vol. 16, part 10, Abstract 1,667. We might name others. These are all references to German scientific publications. We give the reference to the Science Abstracts since you are more likely to have that at hand than the original German publication. The results of these investigations are not in complete accord in the wave lengths and could not be expected to be, as you know.

(12915) M. Z. Asks: Kindly let me know through your correspondance column the correct conclusion to the following experiment. The experiment consists of balancing a 50-centimeter stick which is weighed down on one end. The point where it balances is found to be 39.6 centimeters from one side. Then put a 50-gramme weight on the end of the lighter side. The stick now balances at 32.4 centimeters. The 50-gramme weight took up the space of 2 centimeters on the stick. Now A claims that the weight of the weighted stick originally can be found from this to be 218.1 grammes, which he gets by multiplying 50 grams × 31.4 (distance between centre of weight to point of equilibrium) and dividing by (39.6—32.4) or the distance from the first point of equilibrium to the second point of equilibrium. Also that these 218.1 grammes act as if they were concentrated at the point 39.6. B contends that the first moment is not 50×31.4, but that the weight of 32.4 centimeters of stick must with the 50 grammes be considered as the weight tending to produce the moment of rotation. This multiplied by the distance that the resultant of these forces is from the point 32.4 is the moment. Also he contends that A makes the same mistake in the other arm; and the weight to be considered here is not the weight of the whole stick, but of that arm, and is not concentrated at the point 39.6. A. A is quite correct in his solution of the problem of moments, with a weight upon the end of a 50 centimeters bar, which balances at 39.6 centimeters from the light end, and when a 50-gramme weight is added to the light end balances at 32.4 centimeters from the 50-gramme weight. The answer is 218.055 + centimeters, or 218.1 centimeters as A gives it. It is a universal principle that any body acts as if its matter were all at its center of gravity. This weight is 7.2 centimeters from the last balancing point, and the center of gravity of 50 grammes is at 31.4 centimeters from the balancing point. Then 50 times 31.4 equals 7.2 times the weight of the stick and small weight. This is one of the usual experiments in moments given to students in the high school course in physics, and is not considered a difficult experiment for the beginner.

(12916) M. J. G. asks: Kindly inform me the fusing points of the following metals: plumbago, iron, wolfram, tungsten, nickel. What I wish to know are the fusing points by electric currents. A. We give you the melting points of the substances which you name, as given in the Circular of the Bureau of Standards, No. 35. Iron melts at 1,520 deg. Cent. or 2,768 deg. Fahr. Tungsten or wolfram melts at 3,000 deg. Cent. or 5,430 deg. Fahr. Tungsten and wolfram are the same. Nickel melts at 1,452 deg. Cent. or 2,646 deg. Fahr. It makes no difference what source of heat is employed, electricity or a flame, the substance melts at the same temperature. Plumbago or carbon is not a metal, but its melting point is given as 3,600 deg. Cent. or 6,500 deg. Fahr. for a pressure of one atmosphere. This temperature is given by the electric arc, and possibly by some gas flames. The figures we have given vary somewhat from those given in the textbooks, but they may be assumed to be later and from better determinations. We should consider them as having a higher authority.

(12917) A. C. H. F. asks: Could you furnish me with any information concerning the Tralle and Richter scale as applied to hydrometers. I have sought information in several books, but could find no reference as to the method of graduation of these scales, and I would be greatly obliged if you could send me some information on this subject. A. Tralle's hydrometer is an alcoholometer, and gives the percentage by volume of alcohol in a solution of alcohol and water. It is based upon water at 40 deg. Cent. and a density of pure alcohol 0.7939 at 15.5 deg. Cent. The corrections for other temperatures must be obtained from a table. You will find a good article upon hydrometers in the Encyclopedia Britannica, vol. 14. The scale begins from the density of pure water, and indicates 1, 2, 3 per cent, etc., of alcohol by volume mixed with the water.

(12918) R. H. T. asks: How is the wire wound in such even layers on the magnets used in telephone ringers and on the secondaries of induction coils? A. Wire is wound on the bobbins for the coils of magnets, etc., in the same manner as thread is wound on spools. A machine turns the bobbin and a carrier moves the wire along for each turn of the bobbin as far as the thickness of the wire. At the end of the bobbin the machine feed is reversed and the winding is carried along in the opposite direction. So the wire is wound on in perfectly even layers in a manner impossible to be done by hand. It is done with great rapidity.

(12919) S. de J. asks: Will you be kind enough to let me know what the chemical name is of so-called banana oil, used as a vehicle for gilding? A. The chemical name for banana oil is amyl acetate. It is used in perfumery, the manufacture of mineral waters, and syrups, and in the Heftner lamp as a standard of light, as well as in stains and gilding.

(12920) N. S. asks: Have you any information for making a syrup by adding 6 pounds sugar to ½ gallon of water, and either boiling or dissolving the sugar and placing same in a sealed can, using a process in which it will not ferment or turn back to sugar when in such sealed can, and not use any preservative? A. The only way we know to preserve a solution containing sugar is to sterilize it by heat and seal it air tight in a can. The method is the same as is used in canning fruit. If air comes in contact with the solution, germs of fermentation will surely get in and the syrup will be spoiled.

(12921) I. W. asks: Some time since I received one of your books of formulæ, and I find that the very one I want is a bit ambiguous. I wish you would set me straight. The formula I want to use is the one for nickeling, page 481. Am I to understand that there are three separate baths, First, potash and chlorhydric acid; second, sulphate of copper, sulphuric acid; third, cream of tartar, etc.? The formula also fails to state what sized leaves of zinc to use or how to attach them. Must the zinc be chemically pure or will ordinary commercial zinc do? A. There are three baths in the process of nickeling as given in the "Scientific American Cyclopedia," page 480. The first bath is the cleaning bath, to cut off all the grease and rust and leave the articles so that the metal will adhere as firmly as possible. After they are cleaned they are attached to strips of zinc. Common sheet zinc is employed, nor is a large piece required. A piece 2 inches by 4 inches will answer for a large sized article. Experience will enable you to decide that. In the second bath, as given in the book, an electrical action takes place and the article is plated with copper. The nickel will not adhere well to iron, but copper will adhere well to iron. When the pieces are well coppered, they are red in color, and the third bath of nickel sulphate is used for the final coating with nickel. The after burnishing and polishing is the same as in all work of that kind. We hope this is clear and plain.

THE TRUTH ABOUT THE TITANIC
By ARCHIBALD GRACIE
With 19 Illustrations
Col. Gracie went down with the Titanic; but lived to tell the tale of the tragedy that appalled the world. This book is a complete account of the sinking of the great ship, with innumerable personal references which make the book of absorbing interest, not only to the survivors and to the families and friends of all on board, but to the whole of the vast public which was stirred to its depth by the news of the catastrophe.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The Legal Triumph of the Wrights

THE decision which has been handed down by the Circuit Court of Appeals in the infringement suit brought by the Wright Company settles once and for all, in this country at least, the question: Who invented the flying machine? To be sure, there was never any doubt in the popular mind. Practical achievement counts for so much and paper discussion for so little, that the inventor who rises above the mere theoretical presentation of his ideas is inevitably glorified. The decision of the Circuit Court of Appeals stamps the popular verdict with approval and recognizes Orville and Wilbur Wright as the inventors of the man-carrying, motor-driven aeroplane.

The decision is historically and psychologically interesting because it proves once more how small is the gap between success and failure in invention. Not a single one of the elements in the original Wright machine was new. Chanute had first used the trussed frame with success. Maxim had first placed the horizontal rudder forward. The method of controlling the lateral balance by changing the impact angles of the wings had been proposed over and over again. The vertical rudder was an obvious mechanical expedient for directing the machine in a horizontal plane. Ader and others had proposed or used sled runners. Not a single element in the machine was absolutely novel; yet as a whole it was the most novel mechanism that could be imagined. Not until the Wright brothers appeared had anyone flown successfully in a motor-driven flying machine. Why? Simply because they were the first to recognize the necessity of using the vertical rudder in connection with the wing-warping mechanism in order to prevent the skidding of the aeroplane in straight-away flight—a skidding produced by the increase of resistance on one side and a decrease on the other side in warping the wings. Slight as that discovery seems, it made success possible where only failure had been encountered before.

This is the history of many other inventions. Morse, Bell, Fulton and the rest, all of them seized the abandoned devices of their predecessors and combined them into commercial operative inventions. To the world at large it seems but a little thing to step in this manner from failure to success; yet only a master mind succeeds in grasping the true relation of a dozen mechanical devices, hitherto uncombined, and in uniting them in some brilliant invention for which the world is immeasurably richer.

The decision in the Wright case ought to lay low the idea that the invention of a light gasoline motor made the flying machine possible. If that were really true, the man-carrying aeroplane should have appeared twenty years ago. To be sure, the motors of that period were not light; but on the other hand, the long flights that have been made in recent years with two, three and even five passengers, proved conclusively that lightness of motor was not the only consideration. The Wright brothers succeeded, not because they built a light motor with their own hands, but because they had solved a problem in aerodynamics which had baffled the best scientific thought of centuries.

Tire Failures and Railway Speed

AS the result of its investigation of a derailment which occurred last year at Stockwell, Indiana, the Interstate Commerce Commission came to the conclusion that the accident was caused by a broken tire on one of the car wheels.

A most illuminating and interesting branch of the Commission's investigation of accidents is that which is carried on by the Bureau of Standards, to which sections of broken rails, broken tires or other informing fragments from railroad wrecks are sent, for thorough microscopical, chemical and physical analysis, and the deduction of the proper lesson therefrom. This was done in the case of the broken tire above mentioned, with the result that the Bureau found the breakage resulted from heat cracks which had formed in the tread of the tire.

Now the high temperatures to which car tires are subjected are due to brake action, the heating effects of which are considerably aggravated by the high speed under which modern express traffic is carried on. The heating of the tires depends upon the pressure applied by the brake, the speed of rotation of the wheels, and the time during which the brake is applied. Evidently the greatest heating effect will be produced if the brakes are applied continuously at maximum pressure when the train is running at top speed.

How greatly the heating of the tires is aggravated by high rates of speed is evident if we consider the case of two trains, one of which is running at 80 miles an hour and the other at 60 miles an hour. In this case, since the momentum of the train varies as the square of its speed, the energy transformed into heat at the brake shoes will be twice as great at 80 miles an hour as it will be at 60 miles an hour. If the brakes are applied at full pressure at 80 miles an hour, the train will run over 1,500 feet before the speed has been reduced to 50 miles an hour, that is to say, the train would run for 1,500 feet at an average speed of nearly 65 miles an hour with the brakeshoes on under full pressure.

Hence, during a small fraction of a minute, the greater part of the energy of the moving train is converted into heat on the abutting surfaces of the brakeshoes and the tires. The outer inch or so of the tire is very rapidly raised to a high temperature, and it reaches that temperature quicker than the heat can be conducted to the inner portion of the tire. Now we must remember that the tire was originally fastened to the body of the wheel purely by shrinkage effects, and that when the hot tire cooled, it was thrown into a condition of heavy tensile stress throughout its whole thickness. Hence the theory has been advanced that when the sudden heating of the outer layers of the tire under the frictional contact of the brake takes place, the outer metal of the tire expands and the inner metal has to carry, for the time being, the whole of the heavy initial stresses of shrinkage. A condition may be reached in which the shrinkage tensional stresses are too great for the unheated section of the tire, and in this case fractures, known as thermal cracks, may occur. These fractures may be difficult to detect; and hence there is a call, particularly on high-speed trains, for most careful and systematic inspection.

A Comparison of British and American Battleships

WE publish on our correspondence page a letter in which the writer draws a comparison between the British 25-knot battleships of the "Queen Elizabeth" class and our own latest battleships. He claims that, because the armor of the British ship is thicker (though there is some doubt as to this) the principal gun heavier, and the speed greater, therefore the "Queen Elizabeth" must be a more effective ship than our "Nevada" or "Pennsylvania."

Now the displacement of the "Queen Elizabeth" and the "Nevada" is given as about the same. But this means that when the English ship is loaded with the same proportion of her total amount of ammunition, fuel, stores, etc., as the "Nevada," she will be of considerably greater displacement; for the English displacement, as given in published statements, represents the weight of the ship, not when she is in fighting condition, as it does in the case of the ships of our Navy, but when she has only a limited portion of her fuel and stores aboard.

Now as to the superiority. The English 15-inch gun is of one inch larger caliber than the 14 inch gun carried by the "Nevada." But our correspondent does not know, probably, that the muzzle velocity of the English gun is considerably lower than that of our 14 inch gun; that the energy is not very much greater; and that the penetration at the probable battle range of ten thousand yards is about the same, although the bursting charge of the 15 inch gun, of course, is considerably larger. Furthermore, he omits to state that the "Nevada" carries ten 14-inch guns as against eight 15-inch guns carried by the "Queen Elizabeth." Also, there is reason to believe that the fuel supply of the "Nevada" is greater than that of the "Queen Elizabeth," that is to say, that she could keep the sea longer without calling up the colliers or returning to a coaling station. And, yet again, any one who is familiar, even in a general way, with naval design, knows that the extra weight put into machinery to secure 25 knots as against 21 knots is so great that some other important military element in the ship, such, for instance, as the internal subdivision as a defense against torpedo attack, which in our ships is most elaborately worked out, and is probably more complete than it is in the British ships, must have been sacrificed in favor of boilers and engines.

It is an accepted principle of the tactics of a line-of-battle engagement, that the fleet must be kept together as one unit, the speed of the faster ships being accommodated to that of the slower, so that the latter be not left behind to be cut off and sunk in detail by the enemy. The average speed of the British fleet, like that of our own, is about 21 knots; or, say, 18 to 20 knots in an actual engagement. If the British 25-knot "Elizabeths" are to lie in line with the rest of the fleet, they must not use their highest speed, but must carry within their hulls hundreds of tons of motive power, which they may never be called upon to use throughout the whole engagement.

The British naval staff, in designing these five remarkable ships, has, no doubt, assigned to them some definite work in the strategy and tactics of the various war plans which it is the duty of the staff to formulate and work out. In the absence of knowledge of what these plans are, the ships look to be an odd size—too fast for the first line of battle; too slow for the [illegible]-knot battle-cruiser class.

A New Use for Patents

WHEN the distinguished Dr. Ehrlich, the discoverer of salvarsan, better known as "606," was asked by a German medical association why he had patented his remedy, he replied that he wished to control its manufacture, not in order to make money, but in order to protect the public by guaranteeing its quality. Thus he showed that a professional man may use a patent for a purpose which probably never entered the heads of those who framed the patent laws of civilized countries.

The medical profession, as Mr. Burton Hendricks points out in his article, "The New Medical Ethics," published in a recent number of *McClure's Magazine*, is rapidly abandoning the foolish principle of not patenting its discoveries, for the very reason given by Prof. Ehrlich. It is better to run the risk of being accused of commercialism than of permitting dishonest manufacturers to make a remedy as they see fit. The physician himself cannot guarantee these various products. Hence the need of some method which will insure the public against fraud, and hence the value of patents.

This opens up the question why the patent laws should not be extended to cover discoveries in applied science which cannot now be legally protected. Burbank gives the world a new fruit, a fruit more nutritious, more reproductive, more palatable than any that mankind has known before. It costs him a fortune to experiment before he finally develops it to marketable perfection. No patent laws protect him from the appropriation of his discovery. So, too, the application of Mendelian principles to plant and animal breeding where they involve what may be regarded as the equivalent of invention, should certainly be accorded some protection. Why was not the discovery of Hellrigel that the bacteria nodules on the roots of leguminous plants reduced the nitrogen of the atmosphere in the form of an absorbable nitrogenous fertilizer patentable? Its later improvement has enriched the world by millions. And so we could enumerate a hundred practical scientific discoveries which have enriched the world, but which are now left to the tender mercies of quacks and frauds.

Recovery of Lost Handwriting by Photography

FADED handwriting is perplexing to antiquarians and lawyers and its recovery may be of importance. A recent method depends on the fact that most inks, even ancient inks, are acid in reaction. Nitrated silver chloride paper is kept in contact with the faded text twelve hours or more and then exposed to full light. The action of the acid in the ink on the silver chloride brings about a reaction which is completed by sunlight—reduction to metallic silver which now shows in metallic luster on a dark ground. It is impossible to make this image permanent, but it is legible for a short time. This writing may be made more readily visible by submitting the paper, after exposure, to the fumes of burning phosphorus in a closed box. Another method of developing this image after contact with the faded manuscript is to pour mercury on it from a height of about a foot and then immerse the paper in dilute ammonia. Or the exposed paper may be placed in bright sunlight for fifteen minutes and then pressed against a dry plate which is afterward developed with dilute rodinal. Dampening the faded document permits the aid of a weak solution of hydrogen peroxide.

[illegible]

[illegible] of Mechanical Stoking of Locomotives.—It [illegible] that when a satisfactory mechanical stoker [illegible] large locomotives was developed, it would have [illegible] application. We are informed by one large [illegible] stoker company in this country that it has [illegible] present time over 400 stokers in regular operation [illegible] locomotives in the United States, and that 200 of [illegible] in use on the Baltimore & Ohio Railroad.

[illegible] Blast in Aqueduct Tunnel.—The blast which re[illegible] the last barrier in the Catskill aqueduct tunnel [illegible] by the Mayor of this city on January 11th. [illegible] extends uninterruptedly from the Ashokan [illegible] in the Catskills to the terminal shaft in Flat[illegible] now remains to be lined throughout with [illegible] and when the control apparatus has been [illegible] the aqueduct will be ready for use.

[illegible] From Automobiles in New York City.—The [illegible] of the National Highways Protection Society [illegible] that 25 persons were killed by automobiles in New York city in December. This brings up the total for the year 1913 to 302 fatalities in this city, of which [illegible] 149 were children. In the State of New York, [illegible] of the city, the totals for the year are: auto[illegible], 150; trolleys, 79; wagons, 32.

[illegible] Pelton Wheel in Switzerland.—The hydraulic [illegible] situated on the Lontsch River in Switzerland is [illegible] what is claimed to be the largest Pelton wheel in Europe, the wheel being of 15,000 horse-power capacity. In the same station there are already six Pelton wheels of 6,500 horse-power, so that the addition of the latest wheel brings the output of the Lontsch plant up to 54,000 horse-power and makes it one of the largest plants in Switzerland.

Completion of Mt. Royal Tunnel, Montreal.—On December 10th, 1913, after fifteen months of tunneling through 3 1/10 miles of rock, the railroad tunnel under Mt. Royal, Montreal, was completed. This establishes a record for tunnel building through such material in America. The work was done by the Canadian Northern Railway Company. The excavation of Swiss tunnels has been done in less time, but generally the rock encountered was not so hard as that at Mt. Royal. The present inside measurements of the tunnel are 8 x 12 feet. When the work is completed it will be enlarged to 22 x 30 feet to accommodate two tracks.

Lofty Cantilever Bridge.—A lofty bridge of the cantilever type has recently been completed for the National Railways of Mexico over the Rio Chico on a new line between Durando and Llano Grande. It was planned at first to build a steel viaduct over the ravine, but later the engineers decided to construct a single track cantilever bridge. This structure has anchor arms, 105 feet long, and cantilever arms, each 135 feet in length, carrying a suspended span of 120 feet. The total length of the bridge between back walls is 701 feet 6 inches. The base of the rail is 244 feet above the bottom of the ravine.

Ocean Voyage of Submarines.—The four submarines which left Cuba on December 7th, proceeded under their own power to Cristobal at the Atlantic end of the canal. This trip (700 miles in the open sea) marks an advance in the navigation of submarines. The sea was rough under the influence of strong trade winds during the entire journey, but the boats found no difficulty in maintaining their speed and position for the five days consumed on the trip. The officers and men at the conclusion of the voyage were in as good, if not better, condition than at the outset. The submarines arrived with their fuel bunkers *half* full.

Gatun Lake Reaches Its Full Height.—On December 27th last the elevation of Gatun Lake was 84.76 feet above sea level, which means that it was practically at its normal height. On December 29th one gate of the Gatun spillway was left open throughout the day, and the outflow lowered the surface of the lake to elevation 84 above sea level, at which it will be held until the raising of a low spot at Cano Saddle is completed, and it becomes possible for the lake to rise to its maximum height. All the fourteen gates of the spillway were raised and lowered smoothly, and the tests were regarded as thoroughly satisfactory.

Sanitary Engineering at Harvard University.—Four new courses are offered by the Department of Sanitary Engineering of Harvard University. One will deal with the study, preparation and interpretation of vital, social and sanitary statistics, with special emphasis laid on their application to public health. Another deals with the principle and practice of sanitation and hygiene as applied to the farm, at the summer resorts, in camps, etc. The third course is for students who have never studied bacteriology and who wish to gain a general understanding of the relation of bacteria to the processes of nature, to chemistry, to sanitary science, and to health. A fourth course for specializing in government and business administration deals with the principles of [illegible] and sanitary engineering, with special reference to their administration in cities.

Science

A Uniform System of Shorthand in Germany.—For some time a movement, under government auspices, has been on foot in Germany to unify the various systems of stenography now in use in that country. A committee of 23 experts is now examining proposals submitted by representatives of 40 different systems.

The Antarctic Expedition under J. F. Stackhouse, which is to sail from England next summer, proposes to explore the little-known region between Graham Land and King Edward VII. Land, beginning at the former, and working along the coast, so far as ice conditions may permit. The expedition has opened headquarters in London, at Sardinia House, Kingsway, W. C., and is soliciting contributions.

The Classification of Stellar Spectra, as carried on at Harvard University, was described by Prof. E. C. Pickering at a recent meeting of the Royal Astronomical Society. The task in progress is a vast one, as it will entail the classification of perhaps 200,000 stars. However, about 500 spectra a month are now classified by Miss Cannon and her staff of assistants. Prof. Pickering also described the work of investigating some variable stars of remarkably short period; one of them doubles its light in seven minutes.

A Memorial to Baron Toll, the Russian explorer who, with six companions, was lost somewhere in or near the New Siberian Islands in 1903, is to be erected on the west coast of Kotelnyi Island, from which he embarked on the last known stage of his journey, viz., to Bennett Island. It consists of a tablet bearing a relief portrait of the explorer, with suitable inscription. General interest in Toll has recently been revived by the discovery on Bennett Island, by Lieut. Wilkitsky (or Vilkitskii), of the lost explorer's diaries and collections.

The Pellagra Investigation Committee, of Great Britain, has sent Dr. Louis Sambon to America to study this disease in the West Indies and the United States, with the aid of funds furnished by Mr. N. S. Wellcome and several West Indian governments. Dr. Sambon, who has previously investigated the disease in Italy, does not accept the common belief that pellagra is due to the consumption of damaged maize, but considers it an infection conveyed by an insect, viz., a Simulium, or sand-fly.

Land Reclamation in Holland, a task that has been prosecuted steadily for centuries with such indefatigable energy (the Hollanders boast somewhat irreverently that "God made the world, but the Dutch made Holland"), is still going on as actively as ever. From 20,000 to 25,000 acres of land are reclaimed every year. It is said, however, that more than 250,000 acres of the best soil is still under water, not including the great area under the Zuider Zee, the reclamation of which is a perennial topic of discussion.

The Drought of 1913 in the eastern and central United States was one of the most severe on record. In New York State, according to the *Monthly Weather Review*, the droughty summer was the most severe experienced in at least forty years. It was remarkable both for its duration and for the time of its occurrence, as it began to retard vegetation quite generally by the second week of June and, in spite of occasional rains, became gradually worse until the heavy rains of August 22nd–23rd. The failure of pastures and the drying up of wells and streams never before known to fail were reported from many parts of the State.

A New Idea in Weather Predictions is brought forward by Freiherr von Myrbach in the *Meteorologische Zeitschrift*. Every meteorologist knows that the coming weather cannot always be forecast with an equal degree of confidence; there are times when the current weather chart indicates the conditions that will prevail over a particular region twenty-four hours later with almost certainty, while, on the other extreme, there are weather charts from which prediction is little better than guesswork. The writer suggests that the public could use the weather forecasts more intelligently if the reliability of the latter were in some way indicated by the forecaster, and he suggests a numerical notation for this purpose.

The Crocker Land Expedition, commanded by Donald B. MacMillan, is now in winter quarters at Etah, Greenland, having been prevented by unfavorable ice conditions from crossing Smith Sound to Ellesmere Land, where it had been planned to establish the base. The vessel in which the expedition sailed from New York on July 2, the "Diana," was stranded on the rocks off Barge Point, Labrador, July 17. As she proved to be unfit for further service, the steam sealer "Erik" was chartered at St. John's to take her place, and a new start was made for the North on August 5. Along the Greenland Coast a number of dogs and Eskimo drivers were secured for the expedition. After disembarking the explorers, with their stores and equipment, at Etah, the "Erik" returned to St. Johns. An exploration of the Greenland ice cap is on the programme for the coming winter and spring.

Inventions

Sign-writing Made Easy.—With a view to simplifying and facilitating the preparation of signs and show cards by storekeepers and others, Sidney Hacker of Mt. Vernon, N. Y., in a patent, No. 1,063,969, provides an outline figure or figures suitably formed for manipulation by an unskilled person to aid one in quickly outlining letters or numerals.

A Reversible Moving Picture Film.—Charles E. Dresler and Isaac W. Ullman of New York city have secured patent No. 1,073,411 for a moving picture film which has one series of pictures running lengthwise of it and another series of pictures also running lengthwise of the film, but in the reverse direction, with the pictures of the two series upside down relatively to each other.

An Anti-suction Shuttle.—A patent has been granted to Edwin H Ford of New Bedford, Mass , No 1,071,039, for a hand-threading anti-suction shuttle in which a downwardly inclined passage extends through the wall of the filling runway to the shuttle eye and acts as a vent to avoid the possibility of threading the shuttle by suction.

A Neck-tie that Can be Adjusted.—A neck-tie that can be lengthened or shortened is presented in a patent, No. 1,073,875, to John Calvin Stanford of Atlanta, Ga. The tie has a strip of rigid material secured by a single transverse line of stitching between the ends of the tie so that the material of the tie may be folded over the strip in different directions to effect different adjustments in the length of the tie.

An Electrically Heated Glove.—In patent No. 1,073,926, to Anton Polak of Paris, France, is shown a glove which for the purpose of electrical warming has insulated flexible conductors which serve as heating bodies and are arranged loose alongside of each other and fastened at only a few points to the glove so that their freedom of movement is preserved as far as possible and the extensibility of the glove is substantially undiminished.

An Ozonizing Apparatus.—A patent has been issued to the administrators of Edward Charles Spurge of Niagara Falls, for an ozonizer, whose casing is hollow and constitutes one of the electrodes and is combined with a unitary structure consisting of two dielectrics and an electrode between them, with the unitary structure clamped between the casing parts to provide gaps on each side of the unitary structure.

Applying Wall Paper by Machine.—Patent No. 1,071,812 has issued to Christian J Siebenhaar of Oramel, N. Y., for a wall papering machine in which an extensible frame is provided with means for extending and collapsing it and paper and paste applying mechanism are supplied on a holder, together with devices carried by the extensible frame for pasting the paper on a wall or ceiling.

Some Hydrocarbon Burner Patents.—A series of seven patents, Nos. 1,070,603 to 1,070,609, both inclusive, have been issued upon the invention of Walter E Huenefeld of Cincinnati, Ohio, for improvements in hydrocarbon burners having wick tubes and for laminated shells forming combustion chambers. Patents Nos. 1,070,608 and 1,070,609 have been issued directly to Mr Huenefeld, while the other five are to the Huenefeld Company of Cincinnati as assignee.

An Electrically Operated Safety Razor.—Sampson W. Moon of Chicago, Ill., has patented, No. 1,072,634, an electric safety razor in which the razor head and blade are actuated or vibrated from side to side by electricity, which may be derived from the ordinary lamp socket. The vibrations are lengthwise of the blade so that as the razor is drawn over the face during shaving, the frame and blade are moved rapidly sidewise, giving a saw effect and aiding materially in the cutting of the beard.

A Novel Liquid Meter.—The Leinert liquid meter is an automatic measurer for water, petroleum, sugar juice and other liquids, measurements being made by weight and not by volume, so that temperature does not enter in. It consists of a pair of equal-sized tanks so arranged that when one is filled up to standard level it automatically shifts the feed over to the second tank and is then emptied by siphon recording at each time of filling and emptying. Being actuated by weight of liquid, it is not subject to the sudden inaccuracies of volume meters, and has scarcely any wearing parts. It can also be quickly cleaned and sterilized.

Prize Offered for Improved Horseshoe Design.—It is worthy of note, as probably affecting the roads over which they roll, that the British Roads Improvement Association has offered a prize of £100 for a new or improved type of horseshoe that will provide horses with a satisfactory foothold upon the modern smooth pavements and minimize the damage caused to such surfaces by existing types of shoes. The prize-winning type is to be evolved from open competition. Copies of the rules covering the contest may be obtained by addressing Mr. Wallace E. Riche, secretary of the R. I. A., whose office is at 15 Dartmouth Street, Westminster, London, S. W. There is no entrance fee.

Cleaning Silverware

By L. V. Redman

THE discovery and recent perfecting of electric silver cleaners mark a distinct advance in the art of silver polishing

Silver polishes and cleaners have consisted until very recently of materials which dissolve off the tarnish or cut it off by rubbing with fine powders The black oxide or sulphide which forms as tarnish upon the surface of polished silver appears at first as a film so thin that it displays beautiful iridescent colors of purple and blue; the thickening of the film produces the black oxide color. Solvent polishes are composed of chemicals such as ammonia and cyanide of potash. These chemicals dissolve off the black coating and leave the silver a beautiful satin finish on the surface. The cyanide polishes are very poisonous and should be used only with the greatest caution.

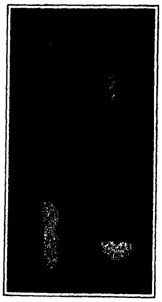
Abrasive polishes are composed of very fine powders and are designed to cut away the tarnish The powders are very hard materials, such as, for example, tripoli, rouge, double floated silica, volcanic ash, kieselguhr, fuller's earth and pumice Each particle as it passes over the surface of the silver cuts off a small part of the tarnish coat, the scratch being too small to be seen by the eye without the aid of the microscope. This method of cleaning silver is very wasteful, as it not only destroys the tarnish, but also destroys or wears away the silver. However, it is the only method which will give to silver that excellent, burnished shield effect, which at times is so much to be desired.

New electric silver polishes are being introduced to the public They are designed to take advantage of the electric current which exists between two metals, when these metals are in contact with each other in water The electric current, which is produced when two metals are in contact in water, is much stronger if an electrolyte like washing or baking soda or common salt be added to the water. The potential is further increased if the water be brought to boiling. Early attempts to make these polishes a commercial possibility were unsuccessful, for the metal used was tin. The water and soda were put in a tin pan and the liquid was brought to boiling. The silver articles to be cleaned were placed in the pan, immersed in the boiling water and in contact with the tin dish. When the pan is new the silver is cleaned rapidly, but the tin soon dies or becomes passive, that is, covered with an insoluble film of tin oxide, which will not conduct the electric current. Once the tin pan becomes passive, it is thrown away and a new one takes its place The fault never lies with the powder. The powder is invariably soda or soda mixed with a little common table salt.

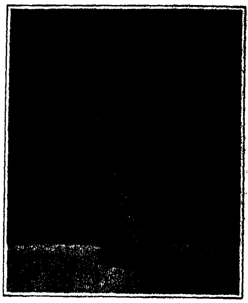
With the introduction of aluminium kitchen utensils another method was adopted for cleaning the silver. The aluminium dishes were used in place of the tin. The voltage is much higher between aluminium and silver; the cleaning of the silver is the matter of a moment if a spoonful of soda be added to the boiling water. The pan will clean the silver if the silver is left in cold water in the pan over night However, this method of using aluminium utensils is not to be recommended, as the vessels are soon blackened on the inside and the aluminium ware is dissolved away by the soda and destroyed.

Aluminium dishes have been made and patented, for the special purpose of serving as silver cleaners. These boxes or pans are fitted at the bottom with rods of zinc which serve as an electric contact between the aluminium and the silver articles. The pans or boxes work fairly satisfactory, and because the zinc rods serve as conductors, they do not go passive or dead as the tin is inclined to do.

Another form of electric polish has been introduced into the market very recently which for cheapness and efficiency is at present unequaled. The powder is put in small packages and is accompanied by a sheet of metal which is an alloy of aluminium and other metals higher in the electric series. All that is needed is a vessel of granite, iron or tin in which water may be boiled. The powder is put into the boiling water and the sheet of metal is thrown in among the silver articles which are being cleaned. The only precaution necessary is to take care that the piece of metal is in contact with the silver. The cleaning is done in a moment and several pieces of silver may be cleaned at the same time. As soon as the cleaning is accomplished the metal should be taken out and washed in hot water and dried, if the best service is to be obtained from it. As these silver cleaners are composed only of washing soda and salt, there is nothing in them injurious to health. The silver after cleaning should be washed in pure hot water and dried, otherwise it may have a slightly yellow color and taste bitter or brassy. These effects are due to the soda which remains upon the surface of the silver and tarnishes it yellow. These electric polishes do not dissolve the tarnish of silver as ammonia and cyanides do. Nor do they wear off the coating of black as the rubbing powders do. The blackened silver is actually reduced to bright metallic silver by this method and is replated upon the silver article. Thus the silver surface is preserved and the life of the silverware prolonged indefinitely by this treatment. Laboratory tests have shown that silver vessels placed in sulphur or sulphides until the silver is blackened and then cleaned by this electrolytic method, do not lose enough silver in one hundred treatments to be detected with a scale which weighs accurately to one two hundred and fifty thousandths of an ounce. The rapidity of the cleaning, the simplicity and the cheapness of the method, and the saving on the silver, should recommend the method to every one interested in silver cleaning.



Tarnished silver partly cleaned by electrolytic process.



Cleaning a knife by immersing it with an aluminium rod in a hot soda and salt solution.

An Electrical Automobile [illegible] System

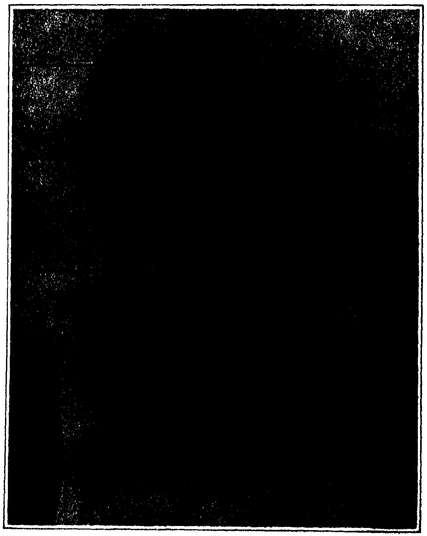
By [illegible] Babcock, M.E.

THERE appeared at the recent [illegible] Grand Central Palace in New York a [illegible] type of electric automobile transmission, [illegible] performing the functions now performed by the [illegible] day type of electric engine starting system. [illegible] apparatus eliminates the usual [illegible] master clutch between the engine [illegible] remainder of the propelling [illegible] well as change gear set and [illegible] wheel. Thus it substitutes for [illegible] gearset and flywheel and [illegible] and their various controls, a [illegible] with a single moving part [illegible] trol lever. With that single [illegible] it is possible to obtain seven [illegible] ratio between the speed of [illegible] crankshaft and that of the [illegible]

In its simplest aspect, the new [illegible] consists of a compact generator, [illegible] wound motor unit and an 18-volt [illegible] pere hour storage battery. The [illegible] can be eliminated, for no reliance is [illegible] upon it for the operation of the transmission; it serves merely as a source [illegible] rent for starting the engine and for carrying the lamp load as in the ordinary electric lighting and engine starting system.

The generator portion of the system has its field mounted in place of the [illegible] engine flywheel which thus is eliminated. The armature is keyed fast to the propeller shaft. The motor unit is mounted just back of the generator with its armature also [illegible] to the propeller shaft, but with its field securely anchored to the chassis frame. The whole, generator [illegible] motor, is completely inclosed in a tight aluminum housing, as is shown by the accompanying illustration, and therefore is thoroughly protected from the insidious action of dirt and moisture and from accidental injury.

The principle of operation can be described briefly as magnetic drag. When the engine is started, the rotating field of the generator exerts a certain drag upon the armature which thus is rotated, carrying with it the propeller shaft and moving the car. The slippage between the field and the armature of the generator is controlled by the simple expedient of varying the strength of the field partly with the aid of resistance, and it is this slippage that affords the change in gear ratio between the engine and the driving axles. Obviously, the slippage results in the generation of a certain amount of current which ordinarily would have to be absorbed by resistance and thus be lost in heat. It is here, however, that the motor unit assumes the place of importance it occupies in the system. Instead of being lost in resistance, the generated current is passed to the motor, which thus becomes a source of energy and assists in propelling the car.



This electrical transmission performs all the functions of an automobile engine starter and eliminates the clutch, changes gear set and flywheel.

When the car is first started—with the control lever in the first speed position—the slippage is at its maximum and hence the maximum amount of current is passed to the motor, the result being that we have a comparatively high torque for starting when it is most needed. As the speeds are "notched up," the motor gradually is cut out of the circuit until at what in the average automobile corresponds to high gear, the motor is virtually dead.

With regard to the amount of slippage that takes place at what may be termed the "high gear" position—and hence the efficiency of the mechanism—it is stated that with the engine crank-shaft rotating at 1,000 revolutions a minute, the speed of the armature will be approximately 960 revolutions a minute. In other words, with the car running on a level road, there is a loss of about 40 revolutions a minute between field and armature. On steep hills, or in sand or mud the slippage may be expected to increase slightly. A fair average would place the efficiency at from 93 to 96 per cent.

As there is no mechanical connection between the engine and the propeller shaft it is evident that an extreme degree of flexibility in the drive must result; it is impossible for engine impulses to be transmitted—a car will run as smoothly, in fact, with three of its four cylinders working as it will with them all firing—

(Concluded on page [illegible].)

Wireless Time

An Interesting Experiment Made at Beloit College

By Dr. E. A. Fath, Director of Smith Observatory

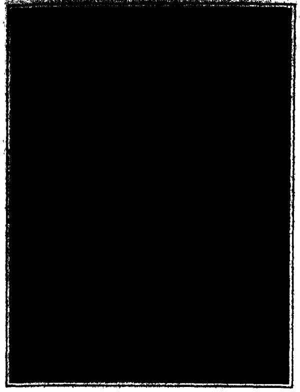


Fig. 1.—The sidereal clock. Note the massive stone pier to which it is attached. Rigidity of support aids in having a clock run uniformly.

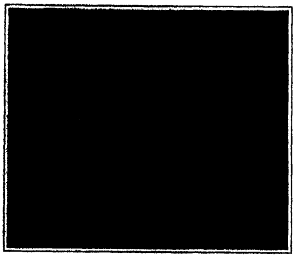

Fig. 2.—The chronograph, for use in recording the instant of a transit.

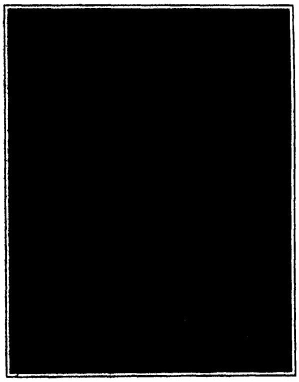

Fig. 4.—The transit instrument. The observer has the chronograph key in his hand to record the time of star transits.

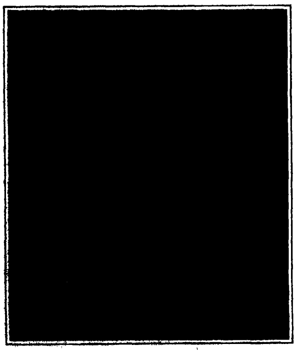

Fig. 5.—The wireless transmitting equipment. The last switch is being thrown before time signals are sent out.

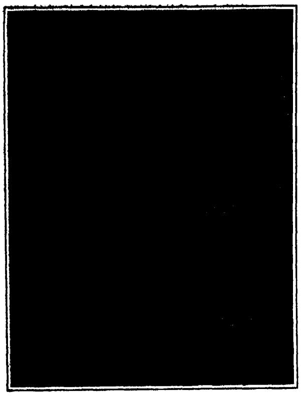

Fig. 3.—The standard time clock. The observer is ready to cut out the required beat during the sending of the signals.

THE determination of time is one of the very practical aspects of astronomy and many observatories are engaged in it to some extent. Up to the present time, it has always been necessary to have direct wire communication with an observatory in order to obtain essentially correct time, but with recent developments in wireless telegraphy the metallic circuit is no longer needed. It is therefore possible for anyone equipped with suitable receiving apparatus to obtain correct time provided some observatory can deliver the proper signals to a wireless transmitting station. Co-operation of this kind has been established in France between the Paris Observatory and the Eiffel Tower radio station, and similar combinations are reported at other points in Europe. So far as known, however, the service to be described in this article is the first serious attempt in this country to send out regular time signals by means of electric waves. The plan originated with Dr. C. A. Culver, Professor of Physics in Beloit College. After he and the writer had carefully gone over the situation and tried out various schemes, the present plan of procedure was adopted. It is the purpose of this article to describe briefly the methods employed.

There are in the sky some hundreds of stars whose positions have been very accurately determined by observations extending over many years. Owing to the rotation of the earth on its axis, stars cross the sky during the night just as the sun does in the daytime. Since the position of these selected stars has been so carefully determined, it is possible to tell with an accuracy of about one one-hundredth of a second when any one of them should cross the meridian, or north-and-south line, of any point whose longitude is known.

In order to utilize these stars a telescope, usually called a "transit instrument" (Fig. 4) is set up so that, as nearly as possible, its line of sight sweeps along a true north-and-south line in the sky. In order that this telescope may be as stable as possible it is placed upon a heavy pier of brick and stone which is built up from a level five feet below the ground level. At the bottom this pier measures 5 by 6 feet and tapers upward to a capstone 2 feet 8 inches square. When this telescope is set for a certain star, the latter, at the proper time, can be seen to come in at one side of the field of view, gradually cross it and finally disappear on the other side. In the field of view, which is faintly illuminated, there can be seen a series of spider threads arranged as shown in Fig. 6. The middle thread is placed as nearly as possible in the center of the field, and, if the instrument is in absolute adjustment, the star crosses the meridian in the sky at the same time it crosses the middle thread. Knowing the exact position of the star, we therefore know the time of transit.

It then becomes necessary to record this instant. This is accomplished by an instrument called a chronograph (Fig. 2). It consists essentially of a rotating cylinder carrying a sheet of paper and a pen which traces a line on the paper. The astronomical clock (Fig. 1) of the observatory is electrically connected with the pen and causes it to break the continuity of the line at each beat (Fig. 7). By means of a telegraph key the observer at the telescope can cause a similar break whenever the star crosses a spider thread. After identifying the various minutes and seconds on the paper it is possible to determine to about one one-hundredth of a second when the observer made the additional break. This time, however, is the clock time. If the record on the chronograph sheet shows the same time as the instant when the star should be on the meridian then the clock is correct, while if not, the difference is the amount the clock is in error.

The actual scheme of observation, however, is not quite so simple as that outlined above. The telescope may not be precisely in the meridian, one end of the horizontal axis of the telescope may be a very little higher than the other, the line of sight may not be exactly at right angles to the axis, the observer may not press his key with sufficient accuracy, etc.* Accordingly, it is necessary to determine whether any of these sources of error exist, and, if so, how much they affect the result. It is therefore customary to observe the transit of a star over a number of the spider threads and also to use from 6 to 10 different stars. Then, by averaging the results, it is possible for a good observer with first-class instruments to determine the error of his astronomical clock to about one one-hundredth of a second.

The time thus obtained is "star" or sidereal time, and the astronomical clock which keeps this time is called a sidereal clock (Fig. 1). Such a clock is always the best in the observatory for it must be depended upon to run with great accuracy during periods of cloudy weather when it is impossible to check it by means of the stars. The highest grade clocks of this kind can be depended upon to one tenth of a second per week. Some have been known to do even better than this.

The average man, however, is not interested in sidereal time, since it is not of direct value to him. What he wants is solar time, and, more particularly, standard time which is now used in almost all civilized countries It is therefore necessary to change sidereal time into standard time. This is easily accomplished by means of suitable tables and a moment's calculation. Then another clock, the standard time clock (Fig. 3) is set to show this time. This clock need be only a fair time keeper, for it can be compared with the sidereal clock and any error easily corrected. At this observatory it is our policy to make such a comparison and set the standard time clock correct to about one tenth of a second just before the daily time signals are sent out.

By means of a simple device, the standard time clock is made to operate a telegraph relay in such a way that each time the clock beats, a circuit is closed, and thus the relay ticks with the clock. This relay, which appears at the right in Fig. 3, is connected by wire to a similar instrument which controls the wireless apparatus of the department of physics in another building.

The accompanying engraving (Fig. 5) shows the radio-transmitting equipment. *A* is a high tension transformer. This is supplied with alternating current at 110 volts and having a frequency of 60 cycles The transformer changes the voltage to about 30,000 and charges the high tension condenser, *B*, seen at the right. This condenser discharges through the usual spark gap and oscillation transformer *C*. The last device changes the frequency from sixty to several hundred thousand per second. The aerial from which the electric waves are radiated into space is 400 feet in length and is connected to the oscillation transformer.

We thus see that the standard time clock at the observatory controls the current which actuates the high tension transformer and therefore the output of electric waves. Each beat of the clock causes a train of waves to be radiated into space. Each group of waves is heard as a single dot at a receiving station so that it might be said, almost literally, that at each station the clock is heard to beat.

---

*As a matter of fact, it is utterly impossible to keep a transit instrument in absolute adjustment. Slight differences of temperature cause varying expansion or contraction of the pier and thus throw it out of level, etc.

The plan of sending time signals which has been adopted for the present is as follows: Each afternoon beginning at 2:55, the clock beats are sent out. The beat is omitted on the 59th second of each minute up to 2:59:50. A break of ten seconds duration is then made which is terminated by a single beat. This beat therefore marks 3:00:00 P. M., and may be considered the essential signal, the others being merely preliminary.

After the switches are thrown at 2:55, everything has been arranged to proceed automatically with the exception of the breaking of the clock circuit for the omitted beats. In a short time this too will be automatic.

For the present, the transmitting equipment is good for about 150 miles during the day, but various changes now under way will greatly increase the range.

One of the advantages of wireless service of this nature is the freedom from interruptions which are common to ordinary wire telegraph systems because of storms, etc. The system is practically independent of weather conditions. It has been in operation since November, 1912, without interruption.

One of the purposes in taking up this work is the collection of data relative to radio-telegraphy by Prof. Culver, from a large number of receiving stations within our radius, which have agreed to furnish periodical reports. It is believed that data of some value can be secured in this way. Time is also being furnished to jewelers and manufacturers who need correct time.

The extended use of wireless time transmission will be of great value throughout the world. While its use on land may become very extensive, yet its principal value will doubtless be on the oceans. On shipboard it will be possible to obtain chronometer corrections to a high degree of accuracy, and this, in turn, will increase the accuracy with which the vessel's position is known. Such knowledge will be of value for charting purposes as well as in times of disaster, when it may mean the difference between life and death.

Recent Improvements in Aeroplane Design and What They Mean

By C. Dienstbach

ALTHOUGH there was seemingly a reason for the complaint that the recent aeronautic "Salon" in Paris showed too little progress, a closer inspection of the fifth of the great French aero shows fails to bear it out. It is true that a weeding-out process has started. The industry has settled down to the practical basis of catering primarily to military requirements, and the number of exhibitors has diminished.

The businesslike apparatus shown gave better proof of real progress than the freaks of former years. While types looked familiar, details of construction had all been developed from long experience in the exacting and practical flying demanded by the military authorities, and designs showed the work of the modern aerodynamical laboratory. This stamps as "practical" some entirely new departures, which looked too modest to command widespread attention, but were really of singular importance. Although inspired by military demands, they will eventually go far in commercializing the aeroplane by making it safer. Thus, an 80 horse-power monoplane ("De Beer") and a 160 horse-power biplane ("Paul Schmitt") were each provided with a perfected mechanism for changing the angle of the planes with the line of the propeller thrust and the fuselage during flight, for the purpose of being able to fly very slowly while making minute observations or dropping bombs and landing on difficult ground. Although any aeroplane can change its angle of attack by operating the horizontal rudder, this primitive method changes the line of the propeller's thrust just as much. The "slipstream" is then turned into a strong descending current which disturbs the normal action of the planes and rudders and impairs their lift. While the propeller itself becomes somewhat lifting, more harm than good is done, because at the steep angle of the planes every ounce of thrust is needed for propulsion. If fast flying did not waste so much power in overcoming the head resistance of struts and wires, which becomes clear gain with that resistance diminishing out of all proportion while flying slowly, the English War Office's prizes for moderately reducing the speed at will could never have been won by the machines competing. (Even the Gordon Bennett aeroplane race is now open only to such fast machines as can likewise cover a slow lap around the course.) With the new arrangement, a speed range of from 19 to 75 miles an hour is claimed for the big biplane.

In landing, the advantage of this arrangement is very obvious. At present the speed must be checked at some altitude when it is still needed for fighting the treacherous gusts of the lower air and in steering around obstacles. It cannot be checked instead just before touching ground (as the birds do) because the long fuselage is in the way. Nor can the machine's rolling after touching be quickly stopped without danger of a somersault while braking on the wheels or on the ground. The new arrangement, supplemented by a reversible propeller, permitting intense aerial braking, would easily provide for birdlike landings on any circumscribed area.

It is most significant that the famous designer of propellers, Chauvière, has brought out a propeller, the pitch of which can be changed during flight. It is only a matter of degree to make it entirely reversible. But before slow flying can reach its full development adjustable planes must be supplemented by changing the propeller's pitch, as actually provided for by Chauvière. It is a well known fact that a motor never develops its maximum number of revolutions while the machine is held stationary on the ground, yet could *do so if the propeller's pitch were reduced for so long.* The pitch must likewise be reduced lest the motor should become powerless in urging the machine against the excessive resistance of the steep planes. Even so, it needs a reserve of power, but surplus power is now so clearly recognised as a necessary condition of fighting the vicissitudes of the air with the primitive machines of to-day, that not a single French aeroplane now lacks a large margin of it. The new arrangements will rather tend to decrease the needed amount. They include also a larger size of propeller, lest in flying very slowly the slip should increase unduly. This requires in turn the efficient gear-drive shown in Caudron's large "seaplane." One of the "baby" Wright racers of 1910, with its enormous twin propellers, furnished a striking proof of the lifting power of a steep angle of the planes, supplemented by suitable propelling arrangements (behind the planes, beside the tail, and with a slow slipstream these large screws impaired the lift but little) when it established a height record in spite of small surface and was seen to start with the shortest run. Very slow flying obviously also demands enlarged rudders.

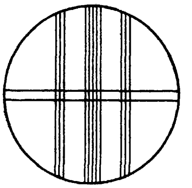

Fig. 6.—The spider threads of the transit instrument. The star is kept between the two horizontal threads so that each star is observed in the same part of the field of view.

Fig. 7.—Part of a chronograph record. The consecutive numbers mark seconds. Two additional signals made by the observer at the transit instrument are shown.

The capacity to fly very slowly and fast at will provides more important advantages than the purely military ones. It permits starting with a very short run (little inertia needs to be overcome to raise the machine) and landing almost without any run. An aeroplane capable of starting and alighting on the roof of an ordinary house certainly goes a long step toward attaining the commercial machine of the future. But still better, it will eventually rob "stalling" and the "airhole" of their terrors. In descending currents a steep angle of attack will supply that sudden increase of lift a gull derives from its characteristic "periods of vigorous flapping." Getting more or less "stalled" means nothing to a machine capable of very slow flight, because little inertia needs to be overcome before it can lift and balance again.

Prize for a Non-Rubber Automobile Tire

THE Austrian War Department offers $10,000 as a prize to be awarded to the person who will, with adherence to certain prescribed conditions, construct an elastic tire for motor trucks. Besides the specific attributes of pure rubber, such as elasticity and adhesiveness, the new material must possess (1) essentially greater durability, or (2) with equal durability the attribute of essentially smaller cost of construction than the rubber tires, thereby reducing the expense of operating motor freight wagons. Its weight must not exceed that of the pure rubber tire. Competitors should hand in a model of the fabric in natural or reduced size, together with drawing and description, at latest by June 30th, 1914, at the *Automobil-Versuchs*[illegible] Division), VI. Gumpendorfer[illegible] ther details may be found in the [illegible] sches, published at I. Graben [illegible], Vienna, [illegible] had also on application in German to the [illegible] ministerium, Vienna, Austria.

The Introduction of Deodar Cedar [illegible] Its Uses

THERE are few trees about which there is [illegible] curious information as the true cedar [illegible] Himalayas. It is called the deodar cedar, [illegible] by some botanists to be merely a variety of [illegible] of Lebanon (*Cedrus libani*). The loftiness and [illegible]ing branches of this tree accord exactly with [illegible]scription of the cedar of Lebanon mention[illegible] sacred writings. The principal difficulty [illegible]ence to its being identical with the true cedar [illegible]anon is that it is not found at present on, [illegible] Mount Lebanon. This does not say that it [illegible] grow there in abundance formerly and subsequently disappeared. In India the tree is held sacred, and [illegible] some places it is not cut except on special occa[illegible], and then only for its wood for incense. The Hi[illegible] call the tree *devadera*, which means the tree of G[illegible].

It is a very large tree, often attaining a total [illegible] of from 100 to 150 feet and a diameter of from [illegible] to 12 or more feet. It has a life equally as long as the *Sequoias* and is tolerant to a marked degree of adverse conditions. It is one of the most drought resistant trees known, and will do better in poor, shallow soil than any other tree that can be made to grow. The deodar is sufficiently hardy to thrive in any part of the United States south of Delaware except at great elevations. Much encouragement has recently been given to its propagation in California, both for shade and ornament and for its timber. In southern California this tree is thriving at points where the thermometer often goes as low as 12 degrees above zero. One thousand deodar cedars have recently been purchased by the city of Los Angeles and planted in Elysian Park, where they are doing well. The city has thus far planted altogether about 10,000 trees of this species in Elysian and Griffith Parks.

About the year 1850 the English government imported an enormous quantity of seed from India and placed it in the hands of nurserymen, to cultivate, on condition that they should return one half of the product to the government at the end of three years. By this means about a million young seedlings of this very valuable tree were planted in England. This is an example well worth following in this country. The establishment of deodar plantations in favorable localities along the Atlantic seaboard of the southern States would serve as a splendid object lesson for those who wish to plant a valuable tree on land that is unfit for farm crops.

The deodar is planted extensively both in India and in Europe, not only because of its very great ornamental value, but also because of the superiority of its wood, which is compact, resinous, highly fragrant, of a deep rich color sometimes resembling polished brown agate. It is also of the most durable nature, instances being on record where its timber, employed in the roofs of buildings, was found perfectly free from decay after a period of nearly two hundred years. The records show that one piece of deodar used as a part of an old bridge in Cashmere, India, at the end of four hundred years proved to be very little decayed, although it was exposed to the action of the water. Pillars of it in the great mosque are said to be of the year 804 Hijri, and those on the Hindu temples are from six to eight hundred years old. Insects do not attack it. It is strong, elastic, and the average weight is only about 35 pounds per cubic foot. The wood has a remarkably fine, close grain, capable of receiving a very high polish, and in India is used for a great variety of purposes. It is used most extensively in the construction of houses and is regarded as one of the best woods for boat and bridge building. It is particularly desirable for the roofing of houses. The wood is very resinous, and is often cut into strips and used as candles.

A New Idea in Moving Pictures

POWERFUL arc lights combined with newly designed moving picture apparatus are used at the Scala Theater in London to produce some wonderful effects, for the persons are seen in life size moving about without the use of any visible screen, so that they appear to act upon a real theater scene which is lighted as is customary in such cases. This remarkable result is brought about by optical combinations which have as yet not been made public. The illusion is heightened by electric devices of an improved kind for working a phonograph together with the moving picture machine so that it always keeps in step, and the words or music are reproduced at exactly the same time as the pictures. It is said that the new apparatus does this with great perfection.

The Architect of the Fisheries Building at the Panama Exposition

To the Editor of the SCIENTIFIC AMERICAN:

In the World's Fair article contained in your valued issue of the 6th ult. I observe that the writer accredited me with having been the "architect" of the Fisheries Building at the World's Columbian Exposition.

As this was in error I desire that the wrong impression be corrected as far as possible, insomuch as Mr. Henry Ives Cobb was architect and I served as designer-in-chief for Mr. Henry Ives Cobb in designing the Fisheries Building, therefore Mr. Cobb should properly be accredited with having been the architect of the structure and myself as designer.

San Francisco, Cal. L. C. MULLGARDT.

Twenty-five Knot Battleships

To the Editor of the SCIENTIFIC AMERICAN:

As to 25-knot battleships, and your recent editorial as to same, you write: "The large amount of weight which must be allotted to the motive power in order to secure 25 knots might better be given to armor protection, or guns. This would be in line with the policy we have wisely and steadily followed, where the speed is moderate and the armor and armament very powerful."

Your article states also that the 25-knot battleships of the "Queen Elizabeth" class have 14-inch armor, and that our latest ships have 13-inch. The "Queen Elizabeth" and sister ships have 15-inch guns. The biggest gun we have afloat or under construction is 14-inch.

The British 15-inch gun weighs 87 tons; projectile, 1,950 pounds. Our 14-inch might be under 60 tons; projectile, 1,400 pounds.

The British ships are several knots faster than ours; notwithstanding this they have heavier armor and bigger guns. The inference in your article is that our policy is to sacrifice speed for heavier armor and bigger guns.

Facts show plainly that the British ships are not only much faster, but have heavier armor and bigger guns. To a layman it is apparent that our ships are badly behind our British cousins in all essentials.

Also read article in same issue of your paper concerning the British battle-cruiser "Princess Royal." And that the speed curves worked out prove conclusively that with the power, said cruiser speed could not have exceeded 30 knots.

We have authentic data concerning other battle-cruisers, including the British "Indefatigable" and "Lion" and the German "Moltke" and "Von der Tann," all of which exceed 29 knots, and going to upward of 33.

San Francisco, Cal. C. P. SLOSSON.

[A discussion of the comparative efficiency of the "Queen Elizabeth" and our latest battleships will be found on the Editorial page.—EDITOR.]

Bacterial Versus Inorganic Fertilizers for the Soil

To the Editor of the SCIENTIFIC AMERICAN:

Mr. C. Cahall, in his article on the ten greatest inventions, as published in the SCIENTIFIC AMERICAN SUPPLEMENT of November 15th, mentions the artificial fixation of atmospheric nitrogen, laying especial emphasis on its relation to agriculture. Mr. Cahall is evidently mistaken as to the field in which the discovery he names will probably find its usefulness; for whatever may be its importance in a military or industrial sense, it is certain that it has little agricultural importance. While it is true that nitrogen is a very important plant food, and a very expensive one if bought in the nitrate *forms*, it is also true that it is so easily supplied from the atmosphere and from decaying vegetation that farmers have ceased considering it among their fertilizer expenses.

In 1886 Hellriegel discovered that certain bacteria found on the roots of leguminous plants had the power to fix atmospheric nitrogen. All leguminous plants share this property. Without the bacteria peculiar to themselves they cannot flourish; with the bacteria they not only flourish, but the nitrogen fixed by bacterial action is, at least in part, immediately available to plants other than the legumes, growing in the same field with them. Given a soil in good mechanical condition, and containing the elements other than nitrogen, a leguminous crop will not only make a good yield, but will, when harvested, leave in the soil sufficient nitrogen to supply a succeeding crop of any other grain. It is a fact well known among orchard men that a crop of peas, beans or vetch planted between the trees will supply them with all the nitrogen they need by fixing it from the free nitrogen of the atmosphere.

Farmers know also that fallowing a field, but especially sowing it to any kind of grass, will result in an increase of soil nitrogen. It may be safely stated that, other things being equal, soil nitrogen is proportional to the humus content of the soil in question, as bacterial action depends largely on the decay of vegetable matter. The place of humus in soil management is too large a matter to be entered into here; but it may be said that without humus there can be little bacterial action, and consequently little fixation of nitrogen. The trouble with commercial fertilizers is that they do not supply humus, and that soil soon becomes mechanically unfit for crop production, and bacterial action stops altogether. This is especially true of the action of the non-symbiotic bacteria, the Azotobacters, which depend for their support upon the carbohydrate content of the soil in which they live. Lipman quotes Kühn as saying that, after growing non-leguminous crops on the same soil (sandy loam) for twenty years, the yields became no smaller, notwithstanding the fact that only non-nitrogenous fertilizers were used. Similarly, in a portion of the Geescroft Field at Rothamsted, abandoned to itself between the years 1882 and 1904, and bearing no leguminous vegetation, there was an average annual increase of twenty-five pounds of nitrogen per acre. These experiments only confirm the experience of every farmer. The best results are obtained from the use of organic fertilizers, as bacterial action of all kinds is thus added.

In farm practice nitrification must be constant. The fugitive nature of nitrate compounds makes it practically impossible to use a sufficient quantity to feed a crop during the growing season, or at most more than a year at a time. On the other hand, atmospheric nitrogen, fixed by the soil bacteria, is constantly renewed and constantly available, but especially during the spring and early summer, when more nitrogen is needed than at any other time. The problem before the working farmer is not to find a new source of nitrogen, but so to manage his soil that he will tap the limitless supply in the atmosphere, and compel it to take its place in the life cycle of his crops, to be liberated and used again and again in the generations to come. Mineral nitrogen is expensive and often unsatisfactory; that derived from the atmosphere is usually a by-product of a profitable crop, and always leaves the soil in good condition. The nitrogen problem has no further meaning to the farmer. R. W. DAVIS.

Moline, Ill.

[We cannot agree entirely with the position taken by Mr. R. W. Davis. While it is perfectly true that a certain amount of nitrogen can be fixed by bacterial agents assisted if necessary by human aid, without the application of nitrogenous fertilizers to the soil, yet it is an undeniable fact that in the present order of things it is customary to apply such fertilizers to the soil, whether in the form of Chile saltpeter, ammonium, sulphate, or what not. Nor is it likely that these methods will ever be entirely supplanted by the bacterial method. For this last is necessarily somewhat slow in its action, and there are many cases in which immediate addition of considerable quantities of nitrogen to the soil is imperative.

Neither can it be said that Chile saltpeter and ammonium sulphate have in the past been applied to the soil merely because they happen to be convenient and available in a reasonably cheap form, and that this practice of using inorganic fertilizers will be abandoned if at any time the cost of Chile saltpeter becomes prohibitive. For at the present day, calcium cyanamide is actually marketed and put on the soil. The technique of cyanamide manuring is, in fact, at the present day well understood, and pretty thoroughly worked out. Cyanamide possesses many properties that render it highly desirable as a fertilizer. It forms an excellent dryer and conditioner when mixed with other fertilizing materials. At the same time there is one limitation to its use, namely, that in conjunction with superphosphates the proportion of calcium cyanamide permissible is limited by the fact that an excess beyond a certain amount tends to cause a reversion of the superphosphates. It may be stated that about 100 to 120 pounds of calcium cyanamide per ton is at present the maximum allowable for use in conjunction with superphosphate. If the phosphorus is applied to the soil in the form of steam-ground bones, somewhat more cyanamide may be used.

The application of nitrogen compounds to the soil directly and the fixation of nitrogen in the soil by the agency of bacteria each has its own special field of usefulness, and we can only gain by giving each of these methods the attention which it so well deserves. —EDITOR.]

The Current Supplement

THE current SUPPLEMENT, No. 1986, contains a remarkable number of readable and highly instructive articles. First of all Noel Deisch discusses the gyroscopic force in revolving cylinder motors and suggests how stability may be improved by altering the position of their axes of rotation.—How a Parsons steam turbine from one of the United States navy destroyers was rebladed is told by N. L. Mosher.—Dr. Felix Oswald's paper on "The Sudden Origin of New Types" is concluded.—To those who are interested in the technical aspects of Pégoud's flights we may commend a scientific analysis of that remarkable aviator's performances which appears in the current SUPPLEMENT.—W. F. Schulz describes stellar photometry by the use of the photo-electric cell.—"A Desolate Island in the Antarctic" is the title of an article by Robert Cushman Murphy, in which the great whaling grounds of South Georgia in the latitude of Cape Horn are picturesquely described.—Among the miscellaneous articles of interest may be mentioned those entitled "The Passivity of Metals," "Winter Troubles on Electric Railways," "Palæobotany: Its Past and Future," and "The Production of Animal Heat."

The Alliance Between Harvard University and Massachusetts Institute of Technology

IN the daily press there have already been set forth the outlines of the plan for co-operation in engineering studies between Harvard University and the Massachusetts Institute of Technology. These are in effect that for the four courses in applied science; namely, mechanical, electrical, civil (to which sanitary engineering is attached), and mining engineering (with which metallurgy is affiliated), Technology in its new plant beside the Charles will direct and actually conduct the studies and investigations, while Harvard will contribute of its funds. The University is to give up entirely its graduate schools of applied sciences (in these branches) and the funds now at their disposal will be paid out by the Bursar of Technology for instruction within Technology walls. The president of the Institute is to be executive head, and the Faculty of the Institute, the board to prescribe courses, etc. The latter is to be enlarged by the addition to it of the instructing staff of the University schools that are to be discontinued.

Efficiency is to be gained by this concentration of effort, an important step forward and in contrast to the prevailing educational custom in America of maintaining at great cost competing courses in the same departments in colleges that serve the same community. It is the community that pays for such things, and educational alliances mean material economies in cash besides those which the union of the faculties entails. With co-operation it is possible for the students of both institutions to have the advantages of strong men for instruction of a quality that it would be folly for each to maintain separately. The Tech.-Harvard alliance means a fuller utilization of the splendid men in both faculties for the benefit of the students in both colleges.

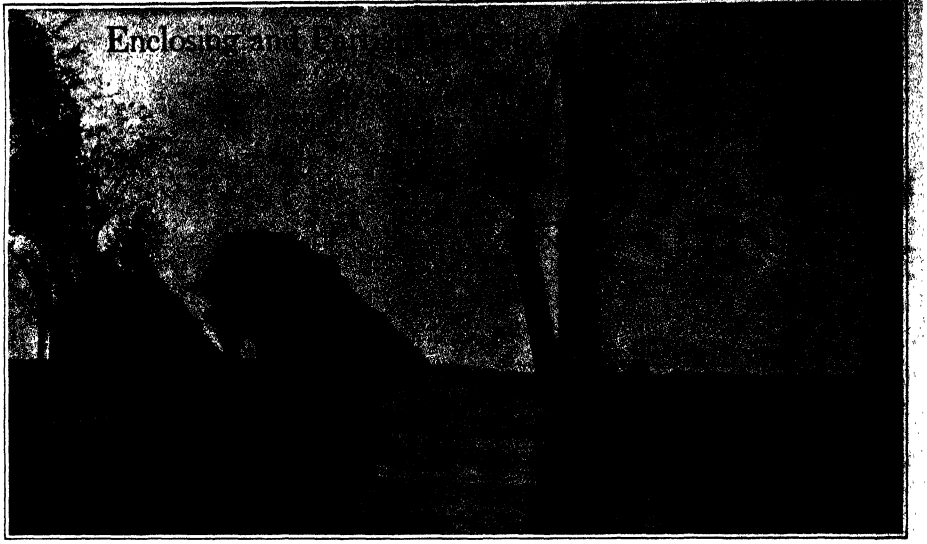
The general story has hitherto been of this nature, the benefit to the community. There is another phase which interests engineers, the question how the students are to be affected. The SCIENTIFIC AMERICAN is pleased to present this side of the case from President Maclaurin's address to the students of Technology at their recent convocation.

Here the terms of the agreement were commented on and three phases considered, the effect with reference to the corporation of Technology, the faculty and the students, respectively The corporation will have from the outset a little more money to spend, though not much comparatively speaking. The annual income of Technology is about $700,000, and Harvard will contribute about one tenth as much. The faculty will be affected only by the addition to its number of a few members from Harvard, not many.

The students of Technology will be affected very little. All the men for the engineering courses will enter the Institute together. At a certain time, as now, the question will be asked as to what course is to be chosen. If this be an engineering course in any of the departments affected, the further question will then be asked, as to which course, Harvard or Technology, is to be taken.

The student pursuing the courses in the Institute alone will not be in any way affected. If he should designate that he intends to follow the Harvard course, or both, which is by no means out of the question, he will then have certain advantages. He can go into the museums of Harvard and study if he wishes He will have the privileges accorded to students at the libraries of Harvard. Among the minor advantages will be the privilege of subscribing to the Symphony concerts in Cambridge, the use of the Stillman Infirmary (on payment of fee) and he can make use of the athletic field of Harvard. Among the important advantages will be the privilege of attending without fee certain Harvard lectures outside of the course selected.

Trunk Manufacturers in Colorado are abandoning the usual basswood and cottonwood for the trunk box, and are turning to Engelmann spruce, which combines lightness, strength, and ease of working.



FOR the benefit of the numerous readers of the SCIENTIFIC AMERICAN, Dr. C. Lely, Netherlands Minister of Waterways, most kindly explained his project for the reclamation of the Zuider Zee to the correspondent of this paper. His Excellency also gave two maps annotated by himself for publication in connection with this article, from which our artist has prepared the accompanying bird's eye view, showing future conditions when the Zuider Zee shall be reclaimed.

The possibility of the reclamation of the Zuider Zee first began to be talked about in 1840. In 1870, a royal commission was appointed to report on the embanking of the southern portion of the sea In 1875 the first sum of money was voted by Parliament to conduct borings in connection with the proposed draining; and in 1877 a bill was introduced for inclosing and draining the southern portion of the Zuider Zee, an area of about 888,000 acres; though this bill was withdrawn by the succeeding cabinet.

April 28th, 1886, saw the institution of the Zuider Zee Association, which has as its object the conducting of technical and financial inquiries about the constitution of an embankment preparatory to a partial draining of the Zuider Zee, the Wadden and Lauwer Zee. It is interesting to note that none other than Dr. Lely was the engineer under whose auspices were conducted all the technical inquiries of the Zuider Zee Association, and that the plan now to be laid before the States General is the identical scheme of the association, amended by the Royal Commission, which was instituted in 1894 to report upon it. Happily for the Netherlands the present year again sees the advent of Dr Lely as Minister of Waterways, and with him comes the most important plan yet proposed by any government, this being in fact the scheme of the Zuider Zee Association, as elaborated by Dr. Lely himself with the amendments of the Royal Commission. Dr. Lely says it will certainly enhance the importance of the country, and increase the means of subsistance of the people of the Netherlands. The greatest difficulty will be the laying of the embankment* of 20,300 meters in length from Ewyk Sluis, near Wieringen, to Piaam in Friesland. This is to be built in water averaging 3.6 meters in depth below ebb level The deepest point, the Amstel Diep, between Wieringen and North Holland, is 10 meters below ebb level. The height of the summit of the embankment is to be 5.2 to 5.6 meters above Amsterdam level. This embankment which is to broaden considerably toward the base is to carry on the inner or Zuider Zee side a double-line railroad and a road for ordinary traffic. Its construction is estimated to take 9 years. It is proposed to commence operations by strengthening the ground on the place where the embankment is to stand, in order to prevent scour when the channel is being closed.

Communication with the North Sea will be by thirty-three 5 by 6 sluice-gates, in the very wide canal to be dug through the Island of Wieringen. The combined width of the sluices will be 300 meters, the depth 4.4 meters, Amsterdam level These sluice-gates will make it possible, in ordinary circumstances, to keep the water level at the present time in the southwestern corner of the Zuider Zee. Besides the thirty-three sluice-gates in Wieringen, there will be two locks, a large one and a small one, for the traffic Within the embankment, four areas are to be drained, each of which is to be apportioned to the province which it adjoins.

I. The northwest area is 54,270 acres in extent. Of this part, 46,800 acres is clay or sandy clay II. The southwest area is 78,800 acres, and of this part 69,560 acres is clay or sandy clay. Both these areas adjoin North Holland. III. The southeastern area adjoins Gelderland. It is 269,410 acres in extent, and of this part 229,977 acres is clay or sandy clay. IV. The northeastern area adjoins Friesland, and is 127,125 acres in extent, and of this part 124,260 acres is clay or sandy clay. The total area of land to be gained is 529,605 acres, of which 486,025 acres is clay or sandy clay. The rest is fen and sand. The area of fertile land will be equal to eleven or twelve times the area of the reclaimed land, known as the Haarlemmer Meerpolder. The depth is 4.5 meters below Amsterdam level, this being a little less on an average than the Haarlemmer Meerpolder. Inside the embankment will be left a large lake, the Ysselmeer, the bottom of which will, for the greater part, consist of sand. Its area will be 358,295 acres. This large lake will be needed to serve as a storage reservoir for the water flowing into it from the Yssel and other sources. It must be large enough to serve this purpose, even when high tides prevent the discharge of water from the lake into the North Sea through the 5 by 6 sluices at Wieringen.

In this way a fresh water lake will be formed, from which the surrounding districts can at all times procure fresh water. In times of drought, in summer north Holland now takes in brackish and dirty water from the North Sea canal and in the north also sea water from the Zuider Zee. Salt water often causes diseases in cattle and is a drawback in cheese making. In dry times Friesland has no supply of fresh water. Owing to the want of grass and water the cattle have to be taken to their stalls and the production of milk becomes smaller. Navigation is hampered in consequence of the fall of the water. The small quantity of water in the canals, etc., soon gets brackish, especially in the west of the province owing to the busy traffic through the locks at De Lemmer, Stavoren and Harlingen. This has a not very wholesome effect upon the cattle and upon the dairy produce, and does a great deal of harm to the fisheries in the inner waters and to several industries, boilers having to be cleaned oftener than when fresh water is used. The large fresh water lake will render possible a more effective draining of the land, because, with a large

supply of fresh water always at hand there can be no harm in letting the water run to a very low level in spring. At present this is hardly possible because summer droughts may cause a scarcity of water. The Ysselmeer will raise the value of hundreds of thousands of acres of grasslands in the surrounding districts by rendering the draining more perfect, preventing want of water and improving the dairy produce. The rise in value will probably amount to from $2 to $4 rent per hectare (2.47 acres). The inclosing will further improve the drainage of some districts because the water level of the Ysselmeer will be less variable, and on an average lower than the Zuider Zee level. The navigation will be rendered safer because the water will be smoother and the Zwolsche Diep will be improved. It will lessen the cost of upkeep of water defenses because long lengths of sea-dyke will no longer be wanted and no damage will be done by floods in Overyssel and the north of Gelderland. Besides all these advantages a railroad connection will be provided between north Holland and Friesland. But the greatest advantage of all will be the acquisition of a great area of fertile land.

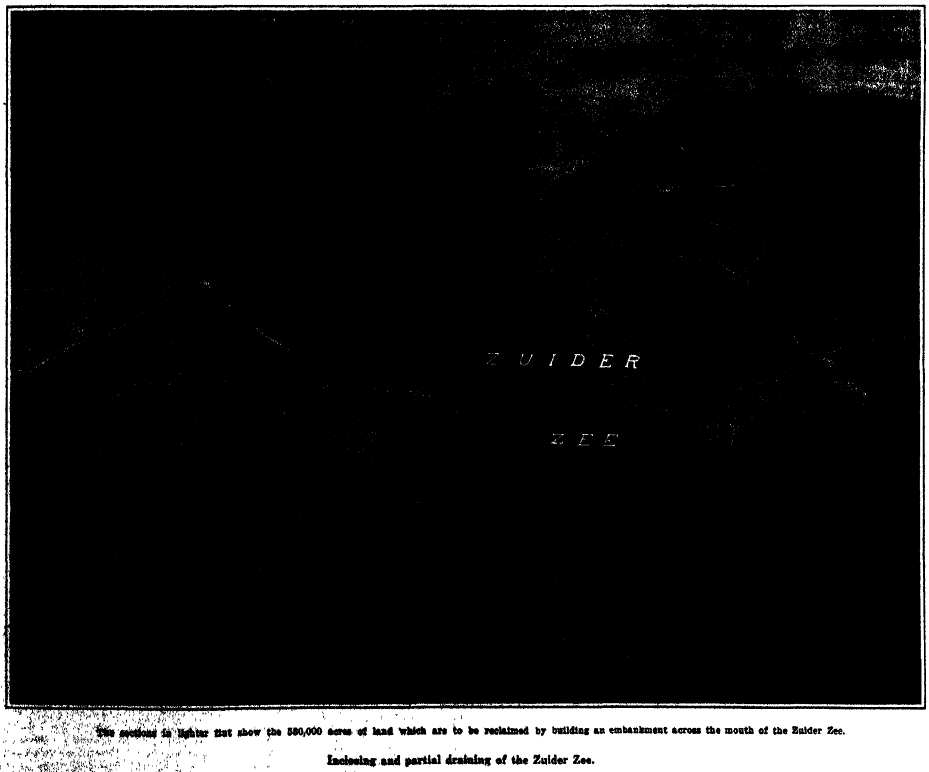
The existing shortage of land, as shown by the annual returns is due to the fact that the increase of the population, both rural and urban, goes on at a much quicker rate than the acquisition of tillable land. Assuming that, as in the case of the Waard and Groet Polders and the Y Polders, very little of the clay in the Zuider Zee Polder will make permanent pasture, the cultivation of the land will require at least 40,000 peasants, including the laborers. To this number we must add peasants families and some 50,000 tradesmen, handicraftsmen, etc., to get the total number of 250,000 workers, who will find ample means of support in the new Zuider Zee province. In 1907 the rent of clayey land in the Waard and Groet Polders was $40 to $60; of light clayey land, $28 to $36 per hectare. In the Anna Pawlown Polder the rent of the light sandy soil was $20, and that of heavy sandy soil $36 per hectare.

Supposing the average rent of the Zuider Zee areas, where the soil will be much like that of the Waard and Groet Polders, to be only $30 per hectare, we may estimate the total amount of the rentals at $6,000,000 a year. The value of the fish caught in the Zuider Zee is a little over $8,000,000 annually. The value of the crops grown on the drained Zuider Zee areas will be $28,000,000 a year. Canals for use in navigation and for the regulation of the water-level will be dug along the coasts in north Holland, coast of Gelderland and that of Friesland.

The time needed for the work will be thirty-three years, and the embankment, which is to be built of sand, will take nine years. By the end of the fourteenth year, the first land will have been reclaimed, in the northwest area, and in the seventeenth year, portions fit for cultivation and habitation will be offered for sale. The cost will not be prohibitive, some $2,400,000 or $2,800,000 annually, the whole cost of the undertaking being estimated at $75,600,000, exclusive of interest; inclusive of cost of military defences, improvement of the Zwolsche Diep, accumulation of capital to defray the cost of dredging sand and silt from the Yesselmeer, compensation to the fishermen, etc. The reclaimed land is to be government property, and it will be offered for sale, but no certainty can yet be given about which system is to be followed in apportioning it.

Many economists are of the opinion that this would be a good opportunity to make a commencement with a system of small allotments which is now deemed so necessary by them, for the welfare of the agricultural population, and for the prosperity of the entire country.

The Latest Change in the Map of Africa is the amalgamation of Northern and Southern Nigeria into the single colony of Nigeria, dating from about January 1st, 1914. The new colony has an area of 332,000 square miles and an estimated population of 18,000,000.



The sections in lighter tint show the 580,000 acres of land which are to be reclaimed by building an embankment across the mouth of the Zuider Zee.

Inclosing and partial draining of the Zuider Zee.

The Gyroscope in China

An Interesting Y. M. C. A. Lecture That Always Fills the House

By Prof. C. H. Robertson

IN China's series of revolutions since 1900 western science and Christian missions have had great influence. The dynamic combination of these two is well represented in the science lectures that have gone out to the distant parts of the Empire-Republic from the lecture laboratory of the National Committee of the Young Men's Christian Associations of China.

No subject has been more popular than the gyroscope monorail car, as is the meaning of the title shown in Fig 1. It is pronounced "Pang hsuan chi tan kuei chue" The magic of this name and the elaborate equipment used to demonstrate its principles have drawn tens of thousands of Chinese students, educators, and officials to applaud the fascinating experiments used in the lectures on this unique subject.

In Fig 2 are shown pieces used to give the underlying principles. The chain on the wheel *A* attached to the rotator shows beautifully the tendency of the links to travel in a straight line due to inertia (the first law of motion). The experiment consists in spinning the wheel up to high speed and then forcing the chain off. When it strikes the floor it does not collapse, but stands up like a hoop made of spring steel and will skip across the stage at high speed until its energy is consumed.

Many interesting and surprising experiments may be made with this one piece of apparatus. For example, if when the chain is forced off, it is caught in a large shallow metal pan, and held at a sufficient slope to prevent the chain running out, it will spin around in a stationary position. If then, the pan be rotated on its center, the chain loop, due to its inertia or persistence of plane, will spin as before and will not be rotated by the turning of the pan.

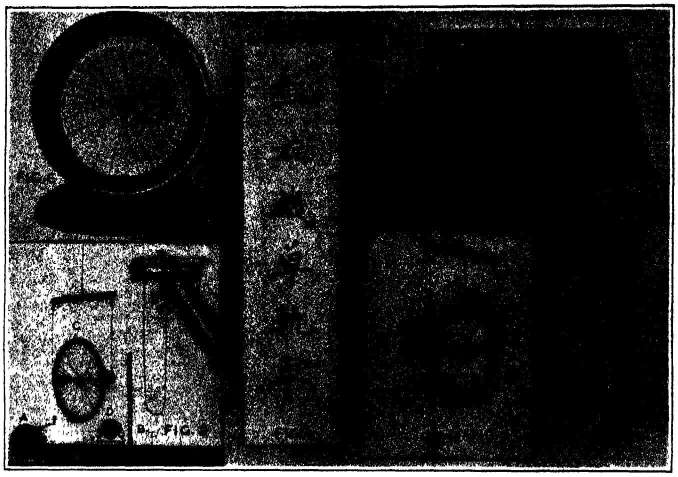


FIG. 1.—The gyroscope monorail car in Chinese. FIG. 2.—Apparatus used in demonstrating the principles of the gyroscope. FIG. 3.—Illustrating the principle of precession in rotation of shaft. FIG. 4.—Showing path of the particles in a quadrant. FIG. 5.—The wrestling gyroscope. FIG. 6.—The construction of the wrestling gyroscope.

Apparatus for a lecture on the gyroscope, used by the Y. M. C. A. of China.

While making some preliminary experiments one day in a long church in the interior of China, the chain was run down from the stage on a board and happened to strike the back of a pew. To the surprise of the writer, it jumped from this to the back of the next one, and the next, and so on, the length of the room. Surprising as it may seem, it will invariably do this if the pews are spaced properly and the chain strikes the first one within a reasonable distance of a certain position and speed. Over a wide range it automatically adjusts itself both as to distance between the seats and as to the distance below its own center at which it strikes. The lower it strikes, the higher and farther will its next jump be. This in turn results in its striking the next one more lightly and not jumping so high, nor so far. After two or three jumps it will come to a state of dynamic equilibrium and skip with great regularity from point to point. This immediately suggested a second experiment—placing a step ladder at an angle of about 30 degrees at the edge of the stage. When the loop strikes the first step, it will jump to the next one, and so on upward until it jumps off the top. This has been an extremely interesting experiment to both Western and Chinese audiences.

If a considerable obstruction, like a folding chair placed upside down, is placed in the path of the loop when running on the floor, it will after striking at high speed, jump several feet in the air, and when it comes down it will not collapse, but will spring up again from contact with the floor, due to what might be called its dynamic elasticity.

The apparatus at *B* (Fig. 2) consists of a larger chain loop suspended by a fine steel piano wire, which may be rotated at high speed through the medium of the flexible shaft, twisted string and rotator. The first effect, due to the tendency of matter to travel in a straight line (centrifugal force), is for the links to move out as far from the center as possible. This still leaves, however, the links at the bottom rotating in small horizontal circles, and it requires but a slight acceleration of speed to cause them to rise in opposition to gravity until the chain is opened out into a complete circle and revolving at high speed in a horizontal plane. It so spins with great steadiness, even though the hand be slid down the wire and much shortening it. If the chain be struck on the side, its circular shape is somewhat altered, but it will so continue with much persistence.

The wheel *C* (Fig. 2) is the result of many attempts to get a satisfactory portable gyroscope of large dimensions capable of being seen clearly by audiences of from one to three thousand people. By reference to the illustration it will be seen that a heavily rimmed wheel is suspended from the ends of a horizontal lever with a fulcrum at the middle. It is used in many interesting experiments. These may begin by clamping the lever across the square frame in place of the chain. If while the wheel stands still one of the end supports be detached, that end of the shaft immediately falls down until it assumes a vertical position. If now the wheel be replaced with the shaft in a horizontal position, and spun up, then when one end is released, instead of falling it immediately begins to precess with the shaft in a horizontal plane. If the speed of precession is accelerated by a little help from outside, the wheel rises up against gravity. If the precession is retarded, it will drop down to a lower plane and will continue these motions for a considerable time. An interesting variation of the same experiment is then made by resting the ball on the end of the shaft in a ball-bearing cup supported by a tripod stand. To hang a large pasteboard box or derby hat over the outer end of the shaft while it is moving around helps a popular audience to realize that there is a remarkable force manifested by such an apparatus.

The audience is always greatly delighted to see some representative from its own ranks trying the strength of the gyroscope by holding the wheel by its shaft, either both hands on one ball or a hand on each ball, and trying to change the plane of rotation at the same time keeping the shaft in a horizontal position. After these preliminary experiments, the mechanism is balanced by sliding the smaller ball (which acts as a counterweight as well) back and forth on the shaft. It will then hang in a horizontal position. If when in this position, and the wheel is standing still, a heavy weight is added to one end of the shaft, that end immediately descends. If now the wheel is spun up and the weight again added, it does not fall, but results in a precession of the shaft about the center of support in a direction depending on the end to which the weight is attached, and the direction of the rotation of the wheel. This leads the way to an explanation of the gyroscope principle.

For this purpose arrows are used, as shown by Fig. 3—*b* represents the direction of rotation of the wheel and *a* the force or weight, which applied to the end of the shaft starts its precession in the direction pointed by the arrow. If now the wheel be considered as divided into four quadrants, *bc*, *cd*, *de*, *eb*, the effect of adding the weight will be to cause the particles in the quadrant *bc* to have a tendency to move out from the plane of the paper toward the reader. This path of the particles is illustrated in Fig. 4. The bead *f* is attached to the wheel, and as it goes through the quarter-revolution from *b* to *c* the resultant tendency due to the weight *a* and the rotation *b-c* is to take up the curved path represented by the white-headed beads going from *b* to *c*. Now if the bead *f* be returned again to the point *b* and we concentrate our attention upon the simultaneous motion of *g* through the quadrant *cd*, we see that, due to the weight *a*, it will first have a tendency to move out from the plane of the frame (which was the original plane of rotation), but due to the fact that the wheel is pivoted on the axis *bd*, it must as a result of the wheel's rotation finally come back again to the original plane of motion at the point *d*. This at once puts us in a position to realize that the path through which the particle *f* in the quadrant *bc* tends to move (due to the action of the weight *a* and the rotation of the wheel) is quite different from that of the particle *g* as it simultaneously moves through the quadrant *cd*. It is of great importance that this be clearly perceived, because the resulting reactions that the particles develop are the forces that make the gyroscope do all of its wonderful and almost incredible antics; and also from which comes its great promise of many practical applications.

This leads to the question, What are the reactions? The question is very simply answered. Particle *b*, when it starts moving from the beginning of the quadrant *bc*, is moving in a definite plane. If at this time the weight *a*, Fig. 3, is applied, tending to take it out of its plane, it will resist by trying to stay in the plane, due to its momentum or tendency to travel in its original plane. This is true of every particle in the quadrant, and the summation of all the reactions in that quadrant may be represented by the arrow *h*. A little consideration will show that for the first part of the quadrant *cd* there is another *force* (represented by the letter *i*), which when the particle starts back toward the plane changes to a force in the opposite direction (represented by *j*).

A more detailed and exact analysis for the quadrant *cd* shows the summation of the forces represented by *j* is a little greater than those represented by *i*, and this is shown graphically by making the arrow *j* longer than the arrow *i*. A moment's thought will suffice to show that the forces in the quadrant *de* (represented by the letter *k*) are equal to and opposite in direction to *h* in the quadrant *bc*; for the quadrant *eb*, *l* and *m* are equal and opposite to *i* and *j* for the quadrant *cd*.

Up to this point we have been considering the motion of the wheel about the axis *bd*. It should be remembered, however, that it is free to move in any direction on any axis, according to forces brought to bear upon it. Let us, therefore, consider the tendency to move about the axis *ce*, Fig. 3. Viewed from this point, we see that in the left half of the wheel *e b c* the summation of the forces is a strong one into the plane of the paper away from the reader, and the summation of the forces on the right half of the wheel *c d e* is a strong one tending to cause the plane of the wheel to move out from the paper toward the reader. If now all these forces *h i j k l m* be replaced by one single force, represented by the arrow *n*, we have arrived at a very important and far-reaching principle—namely, an explanation why, when the force *a* is applied to the shaft of a rotating wheel, the shaft does not move in the direction of the force, but at right angles to it. This conclusion may be stated in the form of a very simple but important rule: "When a force is applied at right angles to the shaft of a gyroscope, the direction of motion of the shaft may be found by rotating the force through 90 degrees in the direction of rotation of the wheel. This second position will be the direction of motion of the shaft resulting from the force." That is, in Fig. 3 force *a* is applied to the shaft when the wheel is rotating in the direction *bc*. If the arrow *a* be turned with the wheel 90 degrees until it comes to *n* it will show the direction the shaft will move. This explains the precession force and direction and puts us in a position at one step to account for the greater mystery of the gyroscope, namely, Why does it not fall under the action of the force *a*? We must remember that the force *a* has developed force *n* at right angles to it and to the shaft; and applying the same rule and the same reasoning up to this point, the force *n* must develop a third force *o*. But one is immediately tempted to ask, Where is this going to end? We begin with force *a* and get a force at right angles to it in the direction *n*; *n* then develops a force at right angles in the direction *o*. The answer is, that the thing ends right there. Because both theory and experiment indicate that, neglecting friction, the force *o* being equal and opposite to the force *a*, they will therefore balance, leaving the force *n* as the one which acts and causes the rotation, which is technically known as precession, at right angles to the first force *a*.

If one wishes further details he may refer back to

The Unsinkable Ship

Notable Naval Architect's Design for a Ship That Will Not Sink

TAKING the "Great Eastern" as its text, the SCIENTIFIC AMERICAN at the time of the loss of the "Titanic" stated that it was entirely feasible to so build large passenger ships that they would not founder even under such severe a mishap as befell the "Titanic."

At the last meeting (December 11th and 12th) of the Society of Naval Architects and Marine Engineers, its vice-president, one of America's best known naval architects, gave a paper with plans entitled "On the possibility of building a large passenger liner that would not, under any of the known mishaps at sea, lose her *buoyancy or stability* and sink."

We present the plans and the following digest of his paper with the conviction that not only would it be unnecessary for such a ship to carry lifeboats; but both in construction and operation it would be an engineering and commercial success.

This paper seeks to point out a possible solution of the problem as applied to a certain type of vessel, viz., the large, modern, passenger liner. New and ever increasing laws concerning life-saving appliances have created a grave problem for the naval architect, both as to carrying heavy top weights and littering a large area of deck space with life boats and rafts. In brief, the suggestions embodied are the fitting of a double upper deck and so arranging the watertight subdivision below the lower member of this deck that the ship would prove both seaworthy and unsinkable under the most aggravated conditions of flooding. The advantages to be considered in this arrangement as opposed to the drawback of wasted space are as follows: The space between the two members of the upper deck would be utilized for cold storage rooms, air ducts, water and steam piping, stores, etc. The fire mains would at all times be under direct control. All horizontal piping and ducts through living spaces would be done away with. Communication to and from engine room, fire rooms, dynamo room, and ventilating and refrigerating rooms would be through a continuous watertight passage fitted with automatic watertight doors which would operate from the influx of the sea.

Section and plan views of an unsinkable ship.

In a ship so constructed and practically, at least, unsinkable, would it be necessary to carry the great number of lifeboats now deemed necessary which, with the great freeboards of our ocean liners, are utterly useless except in the event of a moderate sea and the speedy arrival of assistance?

The question of designing a ship that cannot be sunk by any of the known accidents which befall vessels at sea cannot be treated in a general way. The conditions are so varying in different types of vessels that the only way to handle the subject is to assume a certain type and work out the problem in its relation to the assumption, which is what I propose doing in this paper. I have taken a typical large passenger steamer of the following dimensions:

Length between perpendiculars.......	800 feet
Beam, molded	90 feet
Draught, loaded	33 feet

With a coefficient of 0.64 these dimensions would give a load displacement of 42,180 tons. There would be a complete double bottom, the inner shell being 4 feet from the outer skin, extending from the fore peak to the after peak and up the sides to the lower deck, which would be 15 feet above the base line. The main deck would be 9 feet above the lower deck and the upper deck 9 feet above the main deck amidships and would extend parallel to the base line from frame 87 to frame 233. From frame 87 to the stem, this deck would slope down, touching the stem at a height of 26 feet above base, and from frame 233 it would slope downward aft, touching the stern frame at a height of 27 feet. There would be twelve bulkheads extending from the inner bottom to the upper deck. These would be absolutely watertight, without any doors or openings whatever.

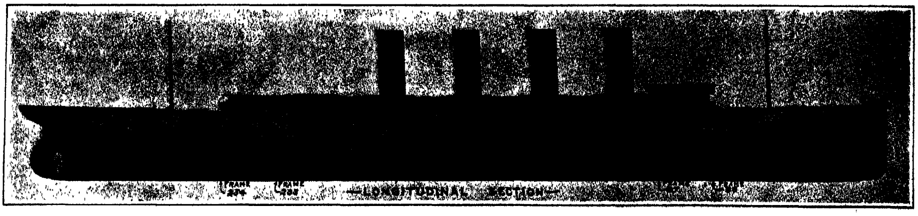
I think it will be admitted that this ship could be considered safe from any injury to the bottom below the lower deck and that danger of sinking would arise from rupture of the skin above the lower deck and under the water line, which is at the upper deck line. Such danger would arise from collision with another ship at such an angle as would cause penetration, or through striking some stationary mass between the lower and upper decks, opening up several compartments to the sea as in the case of the "Titanic."

Let us first consider penetration by collision. Here the damage would be vertical and might, if the striking vessel were large and nearly at right angles, penetrate quite a distance into the side of the vessel. I think, however, that such a disaster could not entail more than three adjacent compartments if near amidships, or say 219 feet 6 inches. What would be the condition with three adjacent compartments near the center of this vessel flooded? The capacity of one of these compartments would be 163,345 cubic feet, from which would have to be deducted the displacement of the boilers, less furnaces, tubes and combustion chambers, or 13,120 cubic feet. The coal capacity would also have to be deducted, for if half the coal were used the vessel would be 3,000 tons lighters, and if the coal were all on board it would displace so much water, and for this we must deduct 52,000 cubic feet and also 1,740 cubic feet for a central watertight passage under the upper deck. This leaves 98,225 cubic feet or 2,806 tons for each of the three compartments that we consider may be possibly injured through collision, or 8,418 tons to be carried by new displacement. In order to provide the displacement for the condition described above, I would propose to fit what I would term a double upper deck, the upper member of which would be 5 feet 6 inches above the lower amidships and parallel to the base line between frames 66 and 254, at which frames it would rise 2 feet and follow the sheer line to the stem and stern. In case of a collision cutting into the upper member of the upper deck the local damage would be confined practically to the depth of penetration and the width of the striking ship, as the space between these decks would be divided into very small compartments both transeversely and longitudinally. As it is, we have between these upper decks 9,730 tons of displacement which, in case of three compartments being opened to the sea, would leave the upper member still materially above the water line. If the injury was near the forward end of the ship, the lower member of the upper deck extending downward reduces the size of the flooded compartments and the displacement of the contents of the holds, at least 50 per cent would still further have to be deducted, while the upper member rising at frame 266 and following the sheer line would provide sufficient displacement to trim ship till water could be introduced into the double bottom aft. These same conditions would apply in case of serious injury aft. It will be understood, of course, that all openings through the upper deck, such as boiler and engine casings and hold hatches, would be watertight structures for at least 16 feet above the load water line.

We come now to another form of disaster, the ripping open of the side of a ship for a considerable proportion of her length by striking the projecting edge of some obstruction under the water line. In the case under consideration this might happen between the lower and the upper deck for a great portion of the vessel's length. The five large compartments would add 14,030 tons to the displacement, while the forward holds, assuming that the cargo occupied one half the space, would add 3,800 tons more, and the after compartments, if they had to be flooded to trim ship, would add 3,400 tons, a total of 21,000 tons. This would sink the vessel 11.86 feet, or 6.36 feet above the upper member of the upper deck amidships, and she would then draw 43.86 feet. This assumption is to the very limit of the possibilities, yet, for an unsinkable ship, it should be provided against in the design. Between the upper member of the upper deck and the shelter deck there should be no air pores or side lights or if lights are fitted they should not be arranged to open and the glass should be cast around a wire mesh as a protection against cracking.

The objection that would naturally present itself to this type of vessel is the apparent waste of space between the upper decks. This space, however, need not be wasted. Forward of frame 66 this space is 7 feet

(Concluded on page 91.)



This ship is rendered safe against either sinking or capsizing by the provision of a double cellular watertight deck at the waterline. If the whole bottom of this ship were ripped open she would settle and ride upon this double deck as upon a second double bottom. Such a ship would be her own lifeboat

General plan for an unsinkable ship.

A [illegible] Electromagnet

By [illegible]

THE most powerful electromagnet in the world was recently installed in the laboratory of Prof. Jean Becquerel, in the Paris Museum of Natural History. This electromagnet, which was constructed by Prof. Pierre Weiss of the Zurich Polytechnicum, is capable of producing a magnetic field of 50,000 gausses, at least.

The three most powerful electromagnets which are now in service—in the laboratories of Prof. Weiss in Zurich, Prof. Kayser in Bonn, and Prof. Ames in the United States—produce fields of only 45,000 gausses.

The great power of the new electromagnet of the Museum of Natural History has been obtained by the use of various artifices, and is the result of a series of improvements. The employment of ferro-cobalt in the construction of the pole pieces contributes largely to the result.

In their study of the ferro-cobalts MM. Weiss and Preuss found that iron, having an atomic magnetic capacity of 11, and cobalt, having a capacity of 9, unite to form a ferro-cobalt of definite composition, which possesses an atomic magnetic capacity of 12. In other words, the magnetic strength of this alloy, when magnetized to saturation, is about 10 per cent greater than that of iron, at ordinary temperatures. Using Swedish iron and commercial cobalt, 98.5 per cent pure, as their raw materials, Weiss and Preuss obtained, in different castings, gains of 9 and 9.7 per cent, instead of the 10 per cent gain of the alloy of definite composition. The ingot that gave the smaller increase, 9 per cent, was more compact than the other, and from it the tips of the pole pieces were cut, as the ingot was too small to furnish material for the whole of the pole pieces.

With these ferro-cobalt tips, separated by an interval of one millimeter, the electromagnet, using 22 kilowatts of electric power, developed a field of 55,000 gausses in the intrapolar space. With iron tips a field of 52,000 gausses was obtained in the same conditions, so that a gain of about 5 per cent resulted from the employment of ferro-cobalt. With the ferro-cobalt tips and an intrapolar distance of 2 millimeters, fields varying in intensity from 42,000 to 49,900 gausses were obtained.

In the last-mentioned case the volume of the intrapolar space amounted to about 14 cubic millimeters, sufficient for the introduction of a spark-gap, a little flame, or an absorbent medium. When the intrapolar space was reduced to 0.5 cubic millimeter, which sufficed for the introduction of a particle of radium, a magnetic field of 75,000 gausses was developed.

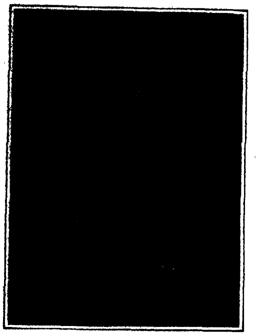
The electromagnet is wound with 1,000 turns of copper tubing, the walls of which conduct the electric current, while the interior serves as a conduit for a cooling stream of water. In order to accommodate the copious flow of water required for refrigeration, the tube is divided into ten sections, which, though electrically connected in series, form ten parallel water conduits. The flow of water is 6 liters per minute and the maximum heating is 50 deg. Cent. The cold water flows first through the innermost tubes, so that the core is always cool. The apparatus attains its normal working temperature in two minutes and maintains it indefinitely. In consequence of this construction it will be possible to operate the new electromagnet continuously for 24 hours. No other electromagnet can be used continuously for more than two hours.

The first experiments that Prof. Becquerel purposes making with this powerful apparatus will have for their object the elucidation of some obscure points in the theory of the Zeeman effect. "It is well known," Prof. Becquerel said to the writer, "that there is something yet unknown in this phenomenon, something that is at the limit of visibility with our present instruments. With the aid of my new electromagnet and its few thousand additional gausses, I hope that I shall be able to make visible this phenomenon, which explains the intimate structure of matter. Molecular and atomic life will reveal, perhaps, part of its secret. When these experiments have been completed I shall continue the study of the effects of magnetic force on matter, in rapid conditions of temperature and pressure."

The hope that an electromagnet of vastly greater power, even of a million gausses, may be constructed by international co-operation in a not too remote future, was expressed at the last International Congress of Electricians. According to Ch. Ed. Guillaume, adjunct director of the International Bureau of Weights and Measures, and M. Jean Perrin, professor of physics at the Sorbonne, the total cost of such an electromagnet would equal that of a modern naval "dreadnought," that is to say, 12 or 14 million dollars, and its construction would require the work of several years.

Still more recently, however, at the Chicago meeting of the International Congress of Refrigeration, the distinguished French engineer and physicist, Georges Claude, proposed to employ low temperatures for the production of an intense magnetic field. The electrical resistance of metals at low temperatures is very small. Hence it should be possible to construct a coil, without an iron core, which would produce at low temperatures a very strong and uniform magnetic field of considerable extent, without employing very strong currents or incurring prohibitive expense.

MM. Kammerlingh Onnes and Georges Claude estimate that twenty thousand dollars would cover the cost of an apparatus capable of producing a field of one million gausses at a very low temperature. M. Claude has subscribed two thousand dollars, and Prof. d'Arsonval two hundred dollars of the required amount.



Prof. Jean Becquerel, who purposes making the first experiments with the new electromagnet.

The new electromagnet of the Paris Museum of Natural History, which produces a magnetic field of 50,000 gausses.

Manufacturers of artificial limbs are seeking substitutes for English willow, used because of its lightness and strength. It is claimed that the Port Orford cedar of the Pacific Coast will prove equally serviceable.

An Extemporized Railway Drawbridge

How They Solved a Knotty Problem at Panama

WHEN the Chagres River at Panama is at flood, it brings down from its upper reaches a large amount of detritus, a considerable part of which consists of a kind of gravel which is dear to the heart of the constructing engineer.

Visitors to the Isthmus who are of an inquiring and observant bent of mind, may have noticed not far above the railroad crossing of the Chagres, certain excavators at work upon large beds of gravel. Now that Gatun Lake has risen to its full height of 85 feet, the Chagres at this point and for many a mile above the railway is submerged; and the clear headway between the water and the underside of the bridge is of course considerably reduced.

Recently it was decided to move a dredge up stream and set it to work excavating from the gravel beds of the Chagres River. The dredge was too high to pass beneath the railway bridge, and the problem arose how to get by the obstacle. It was done in the following way:

Two scows were placed beneath one of the plate girders, and upon these was erected a platform, properly braced and trussed, to receive one section of the bridge. Two locomotive cranes were then run up, one on each side of the span, and the latter was lifted off its bearings on the pier Then the scows with their trucks were floated in beneath the span, and it was towed out of the way until the dredge had passed through. The span was then floated back into position; the two cranes lifted the bridge section from the scows, which were towed out of the way, and the span was then lowered to its footing on the piers.

Floating out a span of the Gamboa bridge of the Panama Railroad to permit the passage of dredges up the Chagres River.

Ozonized Air

IN the *Journal of the American Medical Association* Drs. E. O Jordan and A. J. Carlson publish the results of investigations carried on under a grant from the *Journal* and relating to the bactericidal, physiologic and deodorizing action of ozone Their conclusions are a sweeping arraignment of the now rather widespread use of ozone as a gaseous disinfectant. The writers find that although some bacteria can undoubtedly be killed by ozone, this occurs only when the concentration of the ozone is so great as to be decidedly injurious to man "If disinfection of a closed room without inmates is desired, this can be much more effectively carried out by the use of formaldehyde or some other familiar gaseous disinfectant than by ozone. Ozone has no place in practical room disinfection." As to the weak concentrations of ozone actually used in ventilation, the writers incline to the opinion that, aside from possessing no sanitary value, such use is probably injurious in the long run, especially to persons with weak lungs. Ozone is not an actual "deodorizer" in concentrations that can be employed in practical ventilation. In very great concentrations it seems capable of oxidizing some odorous substances so that the odors are diminished or changed, but the result may be to make the odor actually more disagreeable. However, the deodorizing effect of highly concentrated ozone is due chiefly to the intense odor of the ozone itself, and possibly to the fatigue or anæsthesia it produces in the olfactory epithelium. As a rule such deodorizing is of doubtful utility, and the writers believe that ozone is being used as a means of bolstering up poor ventilating systems.

The Philippine Bureau of Forestry uses a launch for service between islands. The United States forest service employs several, both on inland lakes and in salt water, in Alaska and Florida.

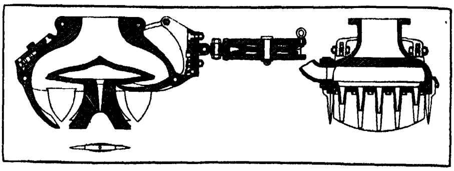
Automatic Drag for a River Dredge

THE ordinary river or pipeline dredge is anchored by a stud or large post which passes through a well in the hull and is driven into the river bottom. The stud then forms a pivot about which the bow of the dredge is swung by means of wire cables anchored at a considerable distance on each side of the bow. The bow of the dredge is swung from side to side in order to bring new sections of the river bed within reach of the suction pipe. The lower end of the suction pipe carries a revolving cage with cutting blades used to scrape and agitate the material that is to be dredged, so that it can be sucked up through the suction pipe. However, the agitating machinery of the suction pipe is somewhat complicated and requires a strong ladder for support and considerable power to drive it, to say nothing of the frequent and vexatious delays for repairs of the complicated mechanism. To overcome those difficulties, Gen. J. W. Sackett has devised a new form of river dredge combining many of the features of the hopper dredge which has a drag at the end of the suction pipe. Instead of moving the whole dredge about on a pivot, he provides for moving the suction pipe with a special form of drag at the lower end.

The form of the drag is shown in the accompanying illustration. It consists substantially of a rectangular bell mouth for the suction pipe; running fore and aft across the bell, is a hollow bar provided with bifurcated blades or teeth. Water is pumped down through a pipe into the hollow bar and issues in jets through openings between the prongs of the teeth. The water jets stir up the material through which the teeth are being dragged. In addition to these teeth, there are four cutting blades secured to the edge of the bell, which aid in confining the loosened material to the bell. In order to trap the material and make sure that it is all carried up the suction pipe, scoops are hinged at each side of the drag. The pulley blocks by which the drag is moved from one side to the other are attached to extensions of the scoops, and these extensions are in turn connected one to the other by means of links, so that when the drag is being pulled to one side the scoop on that side will be swung on its hinges to the folded position shown at the right hand side in the drawing, while the opposite scoop will be swung to open position, where it will be sure to trap the material scraped up by the cutting blades and teeth. When the drag is pulled to the opposite direction, the scoop on that side will hold and the other one will open.

This type of drag has been in use on the dredge "Florida" on the St. John's River for the past few months and has moved far more material per hour than the same dredge formerly pumped up with the standard type of agitating machinery. This dredge does not swing on spuds, as in the case of the usual type of hydraulic dredge. It has four spuds, two on each side of the center line. The port spuds are raised and lowered as the usual spuds. The starboard spuds are inclining, for which purpose the well through the hull is elongated fore and aft When it is desired to move the dredge ahead for another cut, the port spuds are raised, the stern paddle wheel is turned ahead, and the starboard spuds, with the points in the bottom, incline forward until an adjustable stop, abaft the spud at the top of the spud well on the lower deck, engages with the after side of the spud; thus regulating the distance moved ahead. The wheel is stopped and the port spuds are dropped; following which the starboard spuds are raised and assume a vertical position, when they are dropped and dredging is resumed. This operation consumes about forty seconds.

The suction pipe is pivoted on a swiveling elbow. The outboard portion is carried by a horizontal triangular frame, the apex of which is pivoted at the same place as the swiveling elbow. This framework projects over the bow, and the drag is raised and lowered by tackle suspended from a point slightly beyond the frame at the center of its outboard base. At each outboard angle of the frame, posts project downward, which are adjustable as to height and as to various angles with the vertical, and are secured in the position desired. Chains lead from each side of the drag to the foot of each of the posts mentioned and to a convenient place on the frame, where they are made fast. The frame carrying the suction pipe is swung back and forth across the bow of the dredge by means of a wire rope passing along a quadrant on the under side of the frame about midway of its length. By this means a cut 60 feet wide is made. A 10-foot section of hose is provided in the suction pipe of the dredge just beyond the bow of the dredge; which permits sufficient flexibility in the suction pipe to allow the outer end of the pipe to be raised and lowered within such limits as are desired. This apparatus, as arranged on the "Florida," permits dredging to a depth of 20 feet.



Arrangement of the scoop blades and teeth of the drag.

Suggestions for a New United States Patent Office Building

IN reply to a circular letter issued by Mr. E. W. Bradford, president of the Patent Law Association, Mr. G. D. Seymour of the Patent Bar made some very interesting suggestions which should certainly be given every consideration when the location, style and arrangement of the proposed new United States Patent Office Building is eventually decided upon.

Mr. Seymour believes that the building should be placed on Capitol Hill as near as may be to the Library of Congress, and that it should be designed in the Renaissance style and built of white or light colored granite. Thus the building would conform with the public architecture of Washington.

It is suggested that the building should be designed with particular reference to the collection and housing of a great working library, constituting a clearing house, so to speak, of information relating to the useful arts. This collection should contain, for instance, all American and foreign patents, technical works in the field of the useful arts, trade catalogues and all like printed material bearing upon patentable structures, processes, and products.

Mr Seymour believes that the building should also be designed to contain well equipped though not elaborate mechanical and chemical laboratories, where any experiments necessary to be performed in connection with the work of the examiners or tribunals of the office may be carried on.

The Drudgery of Farm Women

PRESIDENT COOK, of the Mississippi Normal College of Hattiesburg, Miss., contends that possibly nine tenths of the drudgery on the farm consists in carrying the water from the source of supply to the point of application and the disposition of the water after use." He points out that a bucket of water contains two gallons and will weigh 20 pounds, and when handled six times the total weight lifted is 120 pounds. He estimates that the use of water in cooking, bathing, scrubbing and weekly washing will raise the lift per day easily to a ton and that this will "take the elasticity out of a women's step, the bloom out of her cheek and the enjoyment out of her soul." He mentions that this daily lift can be eliminated "if the farmer can be brought to see that the farm is also the heir to modern invention," and suggests that an isolated farm can be supplied with a system of water works for an outlay of $250 and that these figures are for first class porcelain lined fixtures. There may be a field here for systematic inventive effort.

The Divining Rod

AT intervals, the divining rod appears in print with its various modifications, and reminds the writer of a story told by a Washington attorney about an applicant for a patent who attempted to demonstrate before the Patent Office Examiner the efficiency of his divining device in discovering gold. He said he was prepared to demonstrate the device, and the Patent Office official placed a small box in the middle of the room for him to sit on and told him he had concealed some gold coin, which he proceeded to "find," but with no success. Then the examiner told him there was a quantity of gold ore in the room, and the inventor, after several futile attempts, failed, and attributed the failure to his exhausted condition from traveling. The device, according to the inventor, indicated the gold ore as located at various points along the walls of the room and the examiner told him finally it was in the box on which he was sitting. The inventor appeared sincere in his efforts, but had evidently been carried away by his enthusiasm and did not again attempt to assert his claims.

Legal Notes

Some Patent Adjudications.—In Reece Folding Machine Company vs. Earl vs. Wilson, the Fenwick patent No. 606,528, for a machine for holding and pressing blanks for collars and cuffs has been held infringed on a motion for a preliminary injunction: the Dormandy patents No. 904,317 and 924,151, for machines for folding and compressing blanks for collars and cuffs has been held infringed on a motion for preliminary injunction and the Reece patent No. 972,916 for a machine folding and pressing blanks for collars and cuffs has been held infringed on a motion for preliminary injunction.

RECENTLY PATENTED INVENTIONS

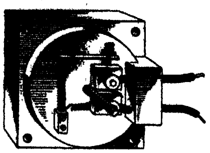
These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

DRESS SHIELD.—H. P. RINDSKOPF, 297 Summer Ave., Brooklyn, N. Y. This shield reinforces the seam or union of the sides of a shield and minimizes the cost of construction incident to the reinforcement. Its two sections are crescent-shaped, having a curved edge to fit under the armpit. The sides are preferably united at the arm seam by adhering the edges of the two sides at the point.

Electrical Devices.

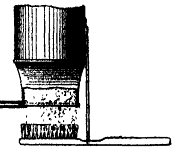
CIRCUIT BREAKER.—A. GUERRA, Celaya, Guanajuato, Mexico. This invention is directed more particularly to a thermo-electric apparatus, though generally relating to electric circuit breakers. It provides a thermally-controlled circuit breaker adapted to open a circuit under certain conditions of load. The apparatus is characterized by a movable element adapted to form part of the circuit, the said element being moved into position to open said circuit through the medium of an expansible rod, the expansibility of which is determined by the heating effect of the current.



CIRCUIT BREAKER.

Of General Interest.

TOOTH POWDER CONTAINER.—W. G. STEADMAN, JR., care of U. S. Navy Recruiting Sta., 161 Griswold St., Detroit, Mich. This invention provides a device for holding tooth powder with means for preventing the mouth of the container from engaging the wet brush, thereby obviating the danger of the power becoming caked around the exit opening in a manner common with the ordinary container. The container distributes the powder evenly on the brush, and means provide for securing economy in the use of the tooth powder



TOOTH POWDER CONTAINER.

Of Interest to Farmers.

BROODER.—J. A. CLARK, Bolckow, Mo. This invention comprises a combined brooder and coop construction which is so mounted as to be automatically actuated by the weight of the chicks it contains, to cause the same to close up and house and protect the chicks when a certain number of the young fowls have entered the same.

Of General Interest.

SURGICAL APPLIANCE.—M. IVERSEN, Stoughton, Wis. More particularly the invention is directed to an improved dropper, which is especially adapted for use in douching. The object of the inventor is the provision of a reversible dropper through which the fluid is adapted to be passed either in large quantities, as in giving enemas, or in certain determined quantities, as in protoclysis. In the use of this appliance there will be no effect of back-pressure on the dropper as the pressure will be the same on both sides; and there will be a free return for the gases and liquids in case of the patient pressing.

FILM PACK.—J. E. PETTIBONE, 4240 Flad Ave., St. Louis, Mo. In this pack the films are attached to a continuous strip so arranged that at no time during the manipulation of the films is there more than a single tab exposed, wherein the moving of each film from exposed position uncovers the succeeding film, the strip to which the films are attached being so folded that each fold when pulled straight, will move the film attached from the point to the rear.

FURNACE FOR TREATING ORES.—J. A. FREY, Silver Spring, Md. By means of this device ores such as those containing sulphur, arsenic, and the like may be treated in order to bring them into a state from which the valuable metals may be readily extracted. Steam is passed into the furnace under high temperature and pressure in order to aid in the treatment of the ores.

BINDING EYELETS.—W. R. INGHRAM, care of Mrs. Eva L. Inghram, 56 E. Wayne St., Waynesburg, Pa. This invention is for use in securing together in book form a series of periodicals, and has for its object the provision of means whereby the members of the series may be connected together in interlocking relation and in such manner that they may be opened in the same way as a book.

ADVERTISING MEDIUM.—G. T. FIELDING, 575 Fordham Road, Bronx, N. Y., N. Y. The intention here is to provide a medium more especially designed for use in show windows and the like, and arranged to effectively advertise a desired line of mechandise by attracting the attention of passersby for a considerable length of time.

VAULT DOOR.—G. W. KENNINGTON, 416 3rd Ave., Brooklyn, N. Y. In this patent the object is to provide a vault door, which is simple and cheap in construction, and which may be readily operated, the door being constructed in a manner that will leave it normally flush with the door frame.

GOGGLES.—L. D. CUTLER, P. O. Main St., Windsor Locks, Conn. In this invention a close fitting of the lenses to the face and especially at the nose is insured to prevent dust or other foreign matter from passing into the eyes of the wearer, and means provide for properly supporting the goggles at the nose without undue strain.

EVAPORATING APPARATUS.—D. COZZOLINO, P. O. Box 465, Escondido, Cal. This invention relates to apparatus for dealcoholizing, condensing, evaporating or distilling liquids, such as beer, ale, stout, malt extracts and the like, and semi-liquids, such as crushed fruit, jams, crushed vegetables and the like.

COMBINATION PIPE AND CIGAR HOLDER.—M. H. BARON, 147 W. Broadway, N. Y., N. Y. This invention provides a smoker's implement comprising a tobacco-holding member, a shield for the same, a mouthpiece associated with the member, and a deflector intermediate the member and the mouthpiece for deflecting the smoke on its way from the member and the mouthpiece.

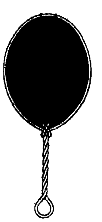
COMBINED CIGAR BOX AND HUMIDOR.—L. BRENAUER, 68 E. 104th St., Manhattan, N Y., N. Y. This invention is more particularly intended for embodiment in cigar boxes, although capable of use for other vendible goods or materials requiring to be kept in a moist condition. It provides an original package in which cigars and other goods may be vended, and having a self-contained humidor, including a removable element having an absorbent material

CORK RETAINER.—O. B. SCHELLBERG, 1058 Southern Boulevard, Bronx, N. Y, N. Y. This invention is characterized by the absence of sharp angles where the different portions adjoin, the structure being further characterised by a gradual curvature between portions extending angularly with respect to one another, whereby in the handling which the device must receive in use the tendency to damage is materially lessened.

COMBINED WORK BAG AND RETICULE.—HELEN H. TERRY, Southampton, N Y The invention refers more particularly to a device which comprises an outer bag or envelop having means whereby it can be closed, and an inner, foldable member having means for carrying different toilet or other articles, and adapted to be disposed within the outer envelop, or withdrawn therefrom to render the articles thereon available for use by nurses, maids and others while traveling, etc.

TRACE AND TUG BUCKLE.—N L ANDERSON, Box 886, Spearfish, S. D. This buckle is for use in engaging a trace and a hame tug. The invention provides a buckle of light construction and simple form, adapted to adjustably receive the trace therein and permit of the ready adjustment of the trace, to shorten or lengthen the same

FLY CATCHER.—MARY C. ARMSTRONG, 225 Kearny Ave, Perth Amboy. N J. Among the principal objects which the present invention has in view are: to provide means for holding adhesive paper or material in a manner to protect the same from accidental contacting with adjacent articles; and to provide a frame for supporting adhesive material or paper for disposing the same in convenient position and for otherwise handling the trap.



FLY CATCHER.

Hardware and Tools.

WATCHMAKER'S TWEEZERS.—H. E. HOLLOWAY, 149 Prospect St., Trenton, N. J. In carrying out this invention use is made of a pair of tweezers which have their clamping ends bifurcated, one side of which is so curved that when the bifurcated ends of the tweezers engage the overcoil end of the hairspring in the watch, they cause the end of the spring to bend in the desired direction while the main portion of the hairspring remains flat on the watch.

Machines and Mechanical Devices.

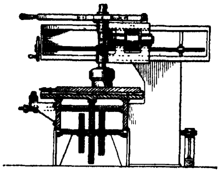
FRICTION CLUTCH—L. A PAGANI, 1031 Willon Ave., West Hoboken, N. J. This invention pertains to machine construction and has particular reference to clutches adapted for connecting one running part, for simultaneous operation, to another part. The object of the invention is to provide a friction clutch provided with novel means by adjusting the gripping shoes.

ARITHMETICAL ABACUS—J M. DE LA ROSA, Arequipa, Peru This invention relates to an arithmetical abacus or device for use in instructing any one, including deaf mutes, in the study of numerals, and it has for an object to provide an improved arrangement of mechanical members on which numerals, fractions, and other information are placed, the entire arrangement being such as to present various information in any desired order

CLUTCH MECHANISM—E. C WILLS, 116 E. Church St., Frederick, Md. This invention refers to clutch mechanisms adapted for general use and more particularly to clutch mechanism used in connection with shafting for the purpose of connecting shaft sections together, and then disconnecting them under such conditions that when connected they will have no slipping movement relatively to each other.

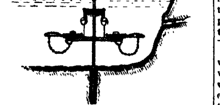
SAFETY ATTACHMENT FOR ELEVATORS.—H. J PIEPGRAS, Caldwell, Idaho. This invention comprises a safety attachment for stopping the elevator in case the load is not removed therefrom before the elevator platform reaches the highest point of its travel, and thus avoiding injury to persons or things on the platform and damage to the elevator parts.

MARBLE SURFACING MACHINE—C H JORDAN, 1015 Birch St., Richmond Hill, N Y., N. Y. This machine grinds the surface of marble or slate slabs down to a true surface and even thickness, and also countersinks to an even depth by means of a heavy iron disk with blocks of carborundum attached. It is also provided with an attachment that can be used for side cutting and molding The table has two speeds—slow for countersinking, cutting and molding, and faster for surfacing The grinding disk is first slid back clear of the table Thus unobstructed, the full size slab of marble or slate is placed on the table, the heavy iron grinding disk with the carborundum blocks is brought forward over the marble slab, the sleeve on the spindle is set and secured so as to grind down to the required depth, the disk rotating is moved back and forth at will and the table on which the slab is placed is moved back and forth in the opposite direction, thus grinding down the entire surface of the slab



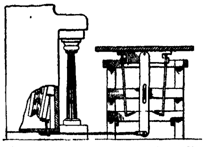
MARBLE SURFACING MACHINE.

STOOL FOR HOLDING TRAPS—W GREEN, Box 70, Holly, Mich This invention is an improvement in stools for holding traps especially for supporting the traps beneath the surface of the water, in position for catching muskrats and the like, and having mechanism for supporting bait in proximity to ordinary steel traps, and so arranged that the animal cannot obtain access to the bait, except by passing over the trap. When the animal scents the bait he tries to obtain the same, and will pass over the adjacent trap to reach the bait As he steps upon the bait pan, the trap will be sprung.



STOOL FOR HOLDING TRAPS.

BELLOWS ACTUATING MECHANISM FOR MUSICAL INSTRUMENTS.—J. P. RAWLS, 1715 Gervais St., Columbia, S. C. This invention relates to means for operating musical instruments, such as organs, player pianos and the like which include power bellows and is in the nature of a player's bench and certain novel connections with the instrument whereby the instrument bellows may be actuated by a minimum effort on the part of the player. It provides a highly efficient construction adapted to support the player of the instrument and to be actuated by a simple body movement of the player without necessitating pedaling of the feet, as is usual.

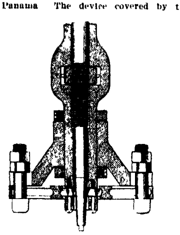


BELLOWS ACTUATING MECHANISM FOR MUSICAL INSTRUMENTS.

Prime Movers and Their Accessories.

HEATING COIL FOR CARBURETERS.—W. A. ERKENBRACK, Box 624, Webster, S D An object of the invention is to provide a coil which may be applied to any suitable carbureter for heating fluid fuel preparatory to its use The device is especially adapted to be used in cold weather when the difficulties of starting internal combustion engines increase in proportion to the decrease in temperature

JOINTING APPARATUS FOR BOILER TUBES—S A DUGAN, Gorgona Empire, Canal Zone, Panama The device covered by this patent is for jointing the tubes of steam boilers to the tube sheets The inventor produces an annular depression in the sheet to receive the tube, and he employs for the purpose a hollow shaft having radially movable cutters, which are gradually expanded by a tapered spindle, the spindle shank being threaded and receiving a nut fitting in a recess in the shaft



JOINTING APPARATUS FOR BOILER TUBES.

Pertaining to Vehicles.

AUTOMATIC PUMP—G J SPOHRER, care of Wilson Motor Starter Co, Franklin, Pa This invention more particularly pertains to a pump adapted to work with an internal combustion engine and more particularly adapted to supply compressed fluid to an automobile for the purpose of supplying energy to actuate an engine starter or to supply a source of power for any other purpose.

Designs.

DESIGN FOR A TOOTH BRUSH—C E. CARROLL, Newport, Ark In this ornamental design for a tooth brush Fig 1 shows a side view, Fig 2 an end view of the same

DESIGN FOR A CLOTHES LINE FASTENER—J MURPHY, 178 Hoyt Ave, Brooklyn, N Y *In this case Fig* 1 is a front view in perspective of a clothes line fastener, showing the new design; Fig 2 is a rear view, and Fig 3 is a cross section of Fig 2 indicating the surface configuration.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

WE wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade mark work. Our staff is composed of mechanical electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States

An Electrical Automobile Transmission System

(*Concluded from page 78.*)

and constant torque on the propeller shaft is practically obtained.

Obviously, the functions carried out in driving the car can in a measure be reversed when the car is coasting with the engine running free. In this case the electric transmission then operates as an efficient brake in which there is nothing to wear. It will hold the speed of the car down to approximately 10 miles an hour on any grade where traction is obtainable.

The operation of starting the motor scarcely can require explanation. Current is drawn from the storage battery and passed to the field of the generator. Normally this would cause the armature to rotate and the car would be propelled backward. But when the brake is set, locking the propeller shaft, the field then rotates about the armature, and thus starts the engine. The electric motor serves a secondary purpose. When the car is driven on what corresponds to high gear, it furnishes current to maintain the battery in a charged condition, the current supplied being at the rate of about 10 amperes. When the car is standing, connections can be established with the control lever which will give a charging rate of up to 30 amperes, this rate being useful after the car has remained idle for a long time or for emergency

The system is not untried, for it has been in use in a car that has been driven for upward of 16,000 miles over roads good, bad and indifferent, practically all over the United States; incidentally, that its efficiency really is as stated is demonstrated by the fact that the gasoline consumption of the car was no higher than that of the ordinary car.

The Gyroscope in China

(*Concluded from page 85.*)

Fig. 4. Considering the motion about the axis *ce*, the motion of the particles in the quadrants are now shown by the position of the black beads, and we quickly arrive at the same conclusion; that the force *n* will develop a similar force *o*. A natural question at this point is: But since the shaft appears to move around in a horizontal circle, its rim does not move out as indicated in the different quadrants. How then can it develop the forces indicated? It is a good question. The answer is that the wheel rim does move out just as assumed. The proof may be had by making an enlarged photograph of the path of the free end of the shaft, and it will be found that it is made of a series of spiral loops If *a* represents the force of gravity, *o* will be equal to it in an opposite direction, thus preventing its falling; and the experimental proof of this is the fact that such a wheel does not fall, but moves off at right angles to the direction of this force, in the direction *n*.

This gyroscope *c*, Fig. 2, also serves to illustrate one aspect of the gyroscope as a compass If after it is spun up, the shaft is placed in a north and south position so that the large ball is pointing toward the north, and it be lifted up by means of the cord attached to the fulcrum at the center of the lever, it may be carried all about the room and swung round several times in each direction, and taken back to the stage, when it will be observed not to have departed from the north and south direction during its journey. This of course does not go into a deep explanation of how the centrifugal force due to the earth's rotation is made to act on a delicate gyroscope to cause it to take up a position so that its axis will be parallel to that of the earth, nor does it explain how the corrections are made due to the forces developed by the motion of the ship carrying it. But it does go a long way toward giving a popular audience an impression of its possibilities in that direction as in the compass so skillfully worked by Mr. E. S. Sperry in America and others in other parts of the world. (See Fig 2.)

Of very great interest also is the gyroscope shown at *D* in Fig. 2. This gyroscope has extended shafts on the horizontal side rings. It is first used without the stilts shown underneath it in the picture. The legs that are extended into sockets at the top of the stilts are sharp. When spun up it balances perfectly on these sharp legs. A weight is added to the cup shown at the side of the frame; instead of sinking down, the side where the weight is applied actually rises. This is due to the fact that in order to stand it must keep its center of gravity over the point of support. The only way to do this is by elevating the side upon which the weight is applied. In Mr. Brennan's monorail car, a large party may stand on one side, then rush in a mass to the other, resulting, not in depressing, but in raising the side to which they go.

This explains also why in rounding a curve the car tips up on the outer side in proportion to the speed and radius of the curve, so that to occupants it is as though the car were traveling in a straight line with the floor level. This is illustrated in this model by replacing the sharp legs by grooved wheels which are capable of running on a wire stretched in the air or laid on the floor as a track. This improvised monorail car will balance itself on such a wire even through a considerable weight is applied to one side or the other. The wire may be swung back and forth, but still it retains its balance without difficulty. After the experiments have been made in this way, the stilts as shown in Fig 2 are then added, and even though they are high in proportion to the size of the gyroscope it is able to stand up and even run on the wire when the grooved wheels are placed at the bottom of the stilts.

The rule above stated is capable of giving a very quick and practical solution of many gyroscope problems; for example, let us apply it to the case of the "wrestling" gyroscope, Fig. 5. This and several other pieces of apparatus used in this article were constructed by Mr. M. M. Wood of Berwin, Ill.

The wrestling gyroscope has been one of the very popular features of the gyroscope lectures in China. Its construction is readily understood by reference to Fig. 6. It consists of a strong bicycle wheel with the rim loaded with lead pipe and then wound with spring brass wire. When spun up to high speed and the case closed and set upon its edge, as shown in Fig. 5, it will stand up with a slight list to one side, and will precess slowly around on a nearly vertical axis. A member of the audience is invited to use a strong staff padded at one end with a solid rubber ball and make the wheel lie down on its side. (See cover illustration.) Any attack upon it above the middle develops a powerful and instantaneous reaction; and unbelievable as it may seem, it is nevertheless a fact that the strongest man is unable to push it over. This experiment delights the audience, and after two men have joined hands and been unable to push the gyroscope over, the audience is willing to accept the statement that a fairly light wheel running at a comparatively slow speed is able to develop a very heavy reaction. The audience then also readily comprehends how it may be possible for a wheel weighing tons and running thousands of revolutions per minute, to furnish a basis for stabilizing a monorail car or opposing the rocking of a ship.

Now how does the precession rule apply in such a case as the wrestling gyroscope shown in Fig. 5? It is seen that the case leans slightly toward and to the left of the reader. The force that is acting upon it is its own weight, which may be represented by a downward force from the ring represented by the arrow *a*. Now if the bottom of the wheel is traveling from the reader, the application of the rule (rotate the force *a* 90 degrees with the wheel) would result in the arrow *a* being rotated to point in the direction *n*. This would cause precession, due to the force *n*, and would result (by a second application of the rule) in the development of a force *o* which would counteract the gravity tendency at *a* and prevent the wheel's falling. Now suppose that a heavy external force is applied, as represented by the arrow *p*. The effect of this would be roughly speak-

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

BUSINESS OPPORTUNITIES

A PRACTICAL gold mining engineer that can command on his report $25,000 cash, wanting to take hold of, develop and operate a splendid gold mining property near Dahlonega, Ga. Can get particulars by writing to me. Letters, not accompanied with references of experience, integrity and financial credit, based on favorable reports, will not be answered. S. A. Jones, Waynesville, N. C.

GENUINE ARCHEOLOGICAL SPECIMENS

A GENUINE Babylonian tablet with cuneiform writing as supplied to Yale University and other Institutions will be sent on receipt of $2. Money back if not genuine or if it does not please you. E. D. Messayeh, 90 Beaver Street, New York City.

INSTRUCTION

FREE TUITION BY MAIL. Civil Service, Normal, Academic, Business, Engineering, Drawing, Agricultural, English, Law, Real Estate and Physical Culture Courses thoroughly taught. Matr $5; Tuition free to first applicants. Carnegie College, Rogers, O.

PATENTS FOR SALE

FOR SALE by owner, June, 1913, U. S patent on simple device for self-clearing salt shaker English and Canadian rights also. M. E. Brooks, Box 274, Cedarhurst, N. Y.

MISCELLANEOUS

HOW TO RUN A LATHE—How to Run a Lathe. A 50-cent book for 10 cents postpaid. For further particulars address South Bend Lathe Company, South Bend, Ind.

INQUIRY COLUMN

Inquiry No. 9346. Wanted the name and address of parties manufacturing tobacco stripping machines, and other machines pertaining to cigar manufacturing and cigar banding machines.

Inquiry No. 9347. Wanted the name and address of an industrial school where shoemaking is taught in all its branches.

Inquiry No 9348 Wanted the name and address of manufacturers having useful household necessities, with a view to obtaining exclusive territory for a house to house canvass

Inquiry No 9349 Wanted the names and addresses of the makers of machinery for making Malt Tonic, also a machine for making grease, and machines for applying plaster (Cement Gun).

Inquiry No. 9350. Wanted the name and address of the manufacturer of a printing press for the printing of tapes for clothing. The machine should preferably be worked by hand

Inquiry No. 9351 Wanted to make some article out of wood which could be made from 2 inch ash, by party having 75,000 or more feet of waste per year which is now used for fuel.

Inquiry No. 9352. Wanted the name and address of a person who is in a position to get the state or county agency for articles of merit that can be sold to business houses or others at $3 00 or over. No kitchen utensils desired.

Inquiry No. 9353. Wanted the name and address of a manufacturer who can make flexible oil cans.

Inquiry No. 9354. Wanted the name and address of a manufacturer of a machine which will stitch silk around small metal rings

Inquiry No. 9355. Wanted the name and address of the maker of triplex glass.

Inquiry No. 9356. Wanted the name and address of a manufacturer who can build an *automobile wheel*, also a *cigar sending machine*. Concerns in the middle West preferred.

Inquiry No. 9357. Wanted the name and address of a manufacturer of a machine for scalloped paper favors and cups

Inquiry No. 9358.—Wanted the name and address of maker of a machine to cut all granulate leather.

$250,000 AVAILABLE FOR EXPLOITING PATENTS IN EUROPEAN MARKETS

From the nature of our business, we are continually approached by investors and others who are anxious to participate in industrial enterprises or purchase patents which are recommended by us.

We are now open to consider, on behalf of a client, the purchase (outright or on royalty basis) of the European rights of a commercially sound and successful article at present exclusively sold in the United States.

We have at command $250,000 for this purpose. Manufacturers who may have neglected the foreign market for patented goods or processes should apply to

THE LETTERS PATENT INSURANCE CO.
Limited
King's House, Kingsway, London, England

[illegible] shown in Figs. 3 and 4 with the accompanying explanation. The experimental proof is the fact that two men are unable to apply enough force at the point p to upset the wrestling gyroscope, which has a total weight of about thirty pounds.

It is always of great interest to the audience to see the experiment made in which, by applying the little finger to the wrestling gyroscope, it is controlled and made to lie down. A very slight pressure applied as shown by the arrow q, with the little finger, is sufficient to overcome the precessional force n due to the weight of the wheel, and it will slowly settle down to the floor in a direction opposite to that shown by the arrow q; for if q be replaced by the equivalent force r and the rule applied, it will show that r will result in a force downward coinciding with a and helping the gyroscope to come to the floor. This also is the explanation of how, by the use of a small lever, a large car like that constructed by Brennan is tipped down to the ground for convenience in loading on freight.

The Unsinkable Ship

(Concluded from page 86.)

6 inches high, increasing to 12 feet at the stem, and could be utilized to receive stores of all kinds, the compartments being only open at certain hours for issuing the day's supplies. The space from frame 254 aft, starting at 7 feet 6 inches and increasing to about 12 feet in height, could be divided into cold storage compartments for all the different kinds of provisions. The space amidships, 5 feet 6 inches high, would form the sub-basement for the hotel part of the ship above. All ventilating ducts, salt and fresh water mains and drainage pipes would be arranged in this space so that only vertical piping would be carried to the rooms. This grouping of all piping and ducts which run horizontally would save much trouble both in the design and working qualities of these systems. This I consider a very important feature in such a design. One of the hardest problems the designer has to face is dealing with pipes and ducts through living quarters, and it is always the horizontal pipes that give trouble. By having the main of these systems between the upper decks where they are accessible at all times without the passenger knowing anything about them, a continued source of dreaded trouble is removed and, furthermore, this would not interfere with the proper subdivision of the space.

Referring to the cross section through one of the boiler compartments, it will be observed that I have provided a longitudinal passage under the upper deck. This passage would be extended through each compartment, from which it would be entered through an air lock, and it would extend from frame 87 to frame 238. In each boiler compartment on each side would be the living quarters for all the men engaged in that compartment. These quarters would be artificially lighted and ventilated. The air would be taken from ducts between the upper decks on the inboard side, discharge at the floor line and would pass up through ventilating pipes on the outboard side. It might be objected that these quarters would be hot in spite of good ventilation. In this connection I consider it quite unnecessary to have much heat in the boiler rooms. The boilers in such a ship would be worked under forced combustion and in that case the fans for forced draught could draw the air from the outer casing round the smokestack and uptakes and discharge it into a casing outside the boiler lagging so arranged that the air would circulate round the boilers on its way to the tubular heaters in the uptakes. Thus any heat radiating through the lagging on the boilers would be taken up by the air for combustion, leaving the fire rooms comfortably cool, and with cold air freely circulated through the living quarters they should be quite comfortable.

The air lock doors into the central passage would be self-closing, balanced doors, easy enough for a man to open but certain to close after him, and it would hardly be possible to conceive of any damage to this passage even from a collision with a very large ship. At both ends of this passageway would be stairs in a water-tight well leading to the shelter deck.

Astronomical Bulls

IT is worth the trouble of studying astronomy just to be able to realize the delicious humor of the blunders committed by non-astronomical people, and especially the journalistic tribe, when they have occasion to discuss the heavenly bodies.

A fresh crop of astronomical bulls is given to the world in a recent number of *l'Astronomie*. After the partial eclipse of the moon of April 1st last, a French newspaper commented thus on the event:

"The phenomenon could be especially well observed because the moon was just at the full last night. What rare good luck for an eclipse!"

In 1911 Brooks's comet attracted more or less attention on the part of the newspapers. *La Presse* of September 28th, 1911, announced that the celestial wanderer "is now to be found in the constellation of Cygnus, three degrees north of Alpha, the upper star of the *Southern Cross*." Of course the cross in question was not the famous asterism of southern latitudes, but that formed by the principal stars of the Swan, lying along the Milky Way.

Of the same comet an Italian newspaper, *La Tribuna* (Rome), gravely stated that at five o'clock in the morning "its tail measures 20 meters long by about 8 meters broad at the end." We fear Mr. Kipling would not have agreed with these dimensions. One could not make much impression on a "ten-league canvas" with so small a brush. Nothing is more common than this habit, on the part of the laity, of estimating the apparent size of celestial objects in terms of a terrestrial scale. It would be extremely interesting to compare such estimates, e. g., of the *diameter of the moon—from* a number of the persons who appear to apply this method of measurement with such facility.

A Parisian newspaper recently undertook to compute the cost of a voyage to the moon, on the basis of current railway tariffs on our planet. The result was somewhat impaired by the fact that the writer confused the distance of the moon with that of the sun.

Why do artists persist in painting the new moon with its horns turned the wrong way? At last we have found a clew to this enigma. It is not merely a little joke on the part of the painters, comparable to the plumbers' time-honored prank of putting the hot-water handle on the cold-water faucet and *vice versa*. The moon represented in these productions is, it appears, not the astronomical moon at all, but the *lune de miel*—a body notoriously exempt from all natural laws. One sees at once the beautiful appropriateness of the fact that the walls of the marriage office at the *mairie* of the fifteenth arrondissement in Paris have just been embellished with a picture of this sort.

An Opinion of the Scientific American

THE *A B C Pathfinder Railway Guide* publishes the following:

"The SCIENTIFIC AMERICAN, which is to the mechanically inclined all that the mariner's compass is to the sailor, has just completed its sixty-ninth year and the *Pathfinder*, but four milestones behind, congratulates its colleague upon its achievements of the past, its standing of the present, and trusts the future will bring it the prosperity it merits.

"Transatlantic travelers do themselves an injustice if they are not equipped with the marvelous compilation known as the SCIENTIFIC AMERICAN Hand-Book of Travel which is a most accurate and complete guide for the amateur or experienced traveler and an invaluable hand-book for the stay-at-home."

ABOLISH TRUCK DELAYS

Firestone Truck Tires and Firestone Quick-Removable Rim Equipment mean the equal of repair shop service in every locality. Firestone Branches and Shop Service Stations have been established throughout the country. But where these have not been installed, truck owners are completely protected against difficulties by a quick-removable equipment that insures fewer and shorter delays.

Reduced upkeep cost and **real truck efficiency** results. All Firestone Tires and Rims are interchangeable on the same felloe bands with all other S. A. E. standard size tires of any type or make.

Firestone

Truck Tires and Quick-Removable Rims

Firestone Notched Tread truck tires for heavy duty give **most** mileage because of continuous base—prevent damaging "traction wave"—minimize vibration—remove excessive strain on any point. They are cured in Firestone Quick-Removable Rims.

Other types of Firestone truck tires represent the same high ideals and proved principle of construction. A tire for every truck, load, road and service condition. "Firestone" should be **your** solution for all truck tire problems. Change to Firestone is quickly made, **to your decided profit and convenience.** Write for catalogue.

Successful men grasp every opportunity for saving time and increasing efficiency

The Busy Man of the Hour

must make every second count. He cannot spare time to read long articles. Still to be successful he must keep in touch with the world's progress, be posted on the most efficient and up-to-date methods. He also requires a certain amount of wholesome entertaining reading. It is for just such men to whom time means both money and opportunity that ***Popular Electricity and the World's Advance*** is published. It tells them tersely yet interestingly of the latest advances of the world today, gives them the gist of current happenings, with time and money saving suggestions applicable to their own affairs. Yet it isn't dry or prosy, but entertaining from cover to cover.

The illustration shows a most efficient application of the automobile phonograph and electricity to the making of an important road survey. This unique combination of modern methods not only resulted in an immense saving of valuable time but in absolute accuracy which it would be difficult to obtain otherwise. An interesting story of this effective method, which can also be applied to other lines of business, appears in

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12922) W. S. asks: Here on Gulf coast the sun rises on 31st June fully 25 degrees north of an east and west section line. Does the sun travel directly east and west on the tropic of Capricorn on the 31st of June? If so, the survey line is not right, for the tropic is south of us. A. The latitude of your place is not far from 30 deg. 15 min. north, and the tropic of Cancer, not Capricorn, where the sun is on June 21st, is in latitude 23 deg. 30 min. north. The sun, which is in the zenith of the tropic of Cancer at noon on June 21st, will be about 6 deg. 45 min. south of your zenith at noon on the same day. The sun rises in the east and sets in the west on March 21st and September 21st to all the world, and only on those days. From March 21st to September 21st it rises to the north of east and sets north of west, and from September 21st to March 21st it rises south of east and sets south of west over all the earth. At your place the sun never travels on an east and west circle through the day. It always moves obliquely up in the forenoon and down in the afternoon.

(12923) I. S. P. asks: Have you a SUPPLEMENT containing the formula for making electropoion fluid used in charging carbon batteries, consisting of sulphuric acid, potash, etc.? A. There are a great variety of electropoion fluids in which the same ingredients are used but in different proportions. A reliable mixture may be made of 40 parts water, 5 parts potassium bichromate and 10 parts sulphuric acid, all by weight. Dissolve the potassium bichromate in the water, heating it if necessary to produce solution, and add the sulphuric acid, pouring it into the solution slowly and with constant stirring. The same weight of chromic acid may be used in place of the potassium bichromate. We send you SUPPLEMENT 792, which contains full instructions for making a very serviceable battery to use with this fluid.

(12924) F. F. D. asks: How much horse-power approximately can be expected from a 40-inch Leffel vertical water power wheel with an abundance of water at 11½ feet head? Is that the kind of wheel to use with such a low head? Could a Francis tube wheel such as shown in your September 13th number be used to advantage? What is the advantage of draft tubes used below the turbine? How do you figure horse-power by the use of friction band (on line shaft pulley) attached to lever which in turn rests on a pair of scales? A. With a 12 inch intake you should develop from 18 to 20 horse-power with a 11½ foot head. With the use of draft tubes a Leffel turbine should be about as efficient as any other, although the writer would much prefer one of the Francis or Fourneyon type. The draft tubes below the turbines, by setting up a suction, convert the head in the outlet channels, which would be otherwise lost, into effective head which is added to the head above the turbine in the computations. The velocity of the pulley rim is measured by a counting apparatus. By the bolt *B* *v* can be made constant at any desired value. By reading the weight *G* on the scales the friction (*F*) becomes known as $Fa = Gb$. Then the work for any unit of time is $L = Fv$.

(12925) J. M. B. asks: Will you kindly state if there is a book published that will give a correct and up-to-date method of honing a razor? A. We do not know any book upon honing razors. Our Scientific American Cyclopedia, price $5, contains several modes of preparing razor paper strops, etc., which we can recommend as good. The only mode of honing a razor of which we ever heard is to lay the razor flat upon the hone and draw it along the hone, turning it over its back for the return stroke. It is usual to draw from heel to point as it is moved to and fro. 2. Is aluminium good? If so, what grade or kind of aluminium is best to use? A. We never heard of aluminium for honing razors. It is much softer than steel and so could not cut down the steel of a razor to a cutting edge. Hones are either oil or more often water stones of a very fine grit.

(12926) M. G. K. asks: If a bowl of water is placed upon a scale and the net weight is exactly 10 pounds (bowl about half full) and a live fish of about 1 pound is added to the bowl of water, is the weight of the bowl of water increased? I have heard that it is not with a live fish, but that it is with a dead one. A. The bowl, water and fish in your question weigh all together 11 pounds, and the scales will indicate that weight whether the fish be alive or dead, or whether a fish, a stone or even water be added to the amount of 1 pound. Probably the reason this question arises so often in the case of a live fish is that the fish does not touch the dish and seems to be borne up by the water. But the level of the water in the dish is raised and the effect is the same as if a pound of water were poured into the dish. If that was done no one would think that the weight on the scales would not be increased, why should they when the fish is added to the matter upon the scales? One pound of fish weighs the same as one pound of water, and affects scales to the same amount.

WHITE TRUCKS PREDOMINATE

During the year of 1913, more White Trucks were purchased, and a greater amount was paid for them, than any other make of commercial motor vehicles. At the present time there are more White Trucks in operation, in both the United States and Canada, than any other make of motor truck.

This leadership in the motor truck industry of America is due to several reasons, chief among which are the following:

1. The most economical truck for the owner, both in gasoline consumption per ton capacity and in cost of upkeep. The slightly additional first cost of White Trucks is paid back to the owner many times over by the saving in operation.
2. The most durable truck in service. White Trucks are constructed of the finest materials known to the science of metallurgy, and the scientifically heat-treated steels used in White Trucks continue to give maximum service long after common materials have worn out.
3. The most reliable truck for continuous operation. Records show conclusively that White Trucks require less attention to keep them in good running order, and lose the minimum amount of time for repairs.
4. Correct distribution of chassis and load weight, affording the least amount of wear on tires, and making them the easiest for the driver to operate. Ease of operation is extremely important in the congested traffic in which motor trucks are used.
5. Simplicity and accessibility of construction, allowing the mechanism of White Trucks to be easily understood and mastered, and quickly reached when necessary.
6. A variety of load capacities suitable for practically all motor truck transportation. White Trucks are built in capacities of ¾, 1½, 3 and 5 tons.
7. Uniform design of all models throughout, making it possible to operate a fleet of various capacity units with the least amount of mechanical problems and supervision.
8. Sound and business-like selling policies, and efficient and business-like service to White Truck Owners after the truck has been purchased. White Service Stations, completely equipped, are located in every center of motor truck operation.
9. The responsibility and firmly intrenched position of The White Company, one of the oldest in the motor industry. Responsible firms prefer to purchase their truck equipment from responsible manufacturers.

These, then, are the principal reasons for the preference given to White Trucks wherever motor trucks are used. The majority of truck users are today buying White Trucks, and those who have experimented with other trucks in the hope of finding something just as good at a lesser price have, sooner or later, purchased Whites. And once White Trucks have been installed, the comparisons are so overwhelmingly in their favor that the remainder of the truck equipment is invariably White.

White Trucks are now used in so many varied lines of service, and under so many different conditions, that data is available for practically every truck requirement.

These Facts and Figures will be gladly furnished upon request

Winter Sports in Switzerland

WHILE Switzerland in summer is famous for her exquisite color combinations, Switzerland in winter charms as a dazzling vision in white. Ice and snow everywhere, glistening and sparkling. Never before has the sun been shining with more brilliancy, never before have the heavens shown a purer and deeper blue. The air is crisp and invigorating, and its effects upon the human body and mind are altogether marvelous.

It is for this reason that many prominent physicians have for the last fifty years been advocating the cause of winter in the Swiss highlands, and Prof. A. Nolda, M.D., a German authority on this subject, recommends it for a great variety of complaints.

The powerfully favorable influence on the nervous system, in cases of anemia, tuberculosis and chlorosis patients has constantly driven more and more neurotic patients to the high mountains. This influence was observed, not only by the doctors, but by the invalids themselves, especially after their return home.

Renewed health and buoyant spirits are the quick results of a sojourn in an Alpine winter station, and with them comes that natural desire to do something. The spirit of pastime is in the air, and very soon we find ourselves speeding down one of those invigorating runs.

Toboggans and bobsleighs of modern construction have ousted the old-fashioned herdsman's sleigh which is now used only by timid beginners. The up-to-date vehicle is the so-called skeleton which is made entirely of iron, weighing about 66 pounds, and on which the rider lies flat, with his head in front facing downward to the ground. For this purpose the iron ribs carry a cushioned board, which, in some types, is built so as to slide backward and forward. The question as to which is preferable, the fixed or sliding seat, is still undecided.

The exact guidance of the skeleton on a quick run requires a considerable amount of technical knowledge; as in simple tobogganing, there exist various guiding methods, which can be used and combined according to requirements. Of these the most important are, the pulling to either side of the front part of the toboggan with the hand and the pressing down the toes of the feet, which as a rule should not touch the ground. The tip of the boot must be protected by a "Bremseisen" (brake iron) a metal plate with sharp steel teeth which is buckled on each foot. The toes also act as brakes The skeleton is designed for great swiftness, but is not very suitable for the ordinary toboggan run. Hence in very many places there are specially prepared skeleton runs, on which the curves are extra highly banked. While the bobsleigh requires a run with a foundation of ice, or a hard frozen snow cover, the first class skeleton run, in order to attain the greatest speed, must be entirely iced.

The most famous skeleton run in the world is the Cresta run of St. Moritz. On the last third of this run, good riders attain a speed of 100 kilometers (62 miles), and more, an hour. Only experts are allowed on the Cresta run.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

One-man Control of the Panama Canal

IT is announced from Washington that the President intends to appoint Col. George W. Goethals as the first governor of the Canal Zone. It is stated that an alternative arrangement was presented by the civilian commissioner at the Zone which contemplated a commission of three. Our President, as usual, has chosen the wiser course. The nation has had considerable experience with commissions at Panama. In the earlier phases of the work, they succeeded one another, after various degrees of failure, and it was only when one strong, capable and understanding man was placed in absolute control that order was brought out of chaos, and the great work of construction began to move with ever lengthening strides toward its ultimate completion.

The United States has learned several lessons from its Panama Canal experiences, and one of the most valuable of these is that among our many great national undertakings there will now and then arise one that calls for a single controlling hand, unhampered by the vagaries and futilities of a commission. It is very fitting, moreover, that the man who has been chiefly responsible for the success of the work should be its first governor. There can be no question that the appointment of Col. Goethals will meet with widespread national approval.

The Safety of Submarines

DEPLORABLE as is the loss of life, amounting in the past ten years to some 200 officers and men, which has occurred through accidents to submarines, we must not allow these disasters to shake our faith in the efficiency and safety of the modern up-to-date vessel of this type.

In the first place, it is significant that of the seventy-seven men that have been lost in the British service, the greater part have gone down in submarines of the earliest type built for that navy, and known as the A-1 class. So, also, the disasters in the French navy have generally happened to submarines of the earlier and more or less experimental types. That even these cruder vessels can be operated with safety is proved by the fact that we have in our own navy several submarines of practically the same design as those that have been lost in the British navy, and yet we have never lost a submarine, nor the life of a single man.

The submarines which have been built during the past four or five years, and those now under construction, are greatly superior to the first smaller vessels. As a matter of fact, among our own officers it is considered that no special risk attaches to submarine service. Our submarine flotillas come and go as they please, and do not hesitate to make extensive deep-sea voyages; as witness the recent 700-mile trip of several of these craft from Cuba to the Atlantic entrance of the Panama Canal.

An Ill-considered and Pernicious Bill

MEASURES of unbelievable inconsistency have occasionally been passed in the halls of Congress; but we doubt if those august chambers have ever witnessed such an act of stultification as was perpetrated by the recent passage in the Senate of what is known as the Seamen's Bill. We speak advisedly, for what other term than stultification can be applied to the action of the Senate when it deliberately passes a bill which is so drawn as to completely defeat the very object at which it aims? The bill in question is designated as "An act to promote the welfare of American seamen in the Merchant Marine of the United States; to abolish arrest and imprisonment as a penalty for desertion and secure the abrogation of treaty provisions in relation thereto; *and to promote safety at sea.*"

Surely it will be agreed that the last named object, "*safety at sea,*" *is far and* away the most important of those named in the bill. Everyone has a kindly feeling toward the men that "go down to the sea in ships;" and there is not a taxpayer in the United States who would not welcome with pleasure any legislation that would tend to make their lot easier and their daily life upon the sea more attractive. But when it is sought to do this at a sacrifice of those stringent safeguards of discipline upon which the security of the ships, of their cargoes, and, above all, of their passengers, depends, it is time to call a halt and subject such remedial measures to very close and critical examination.

It is not any desire to humiliate the seaman or exalt the position and prerogative of the officer that has evolved, in the course of centuries, the strict laws which now obtain in the merchant marine against insubordination or desertion; yet we are compelled to admit that a candid and impartial study of the wording of this act leads us to the conclusion, not only that it will fail to benefit the seaman, but that it will greatly impair the efficiency of the crews and most seriously interfere with the safe and efficient working of the ship. Should this act become a law, the only punishment for desertion will be forfeiture of the effects the seaman leaves on board and of such wages as are due him. For neglecting to join his vessel or to proceed to sea, for absence without leave within 24 hours of the vessel's sailing, or for absence at any time without leave, he is to be punished merely by forfeiture from his wages of not more than two days' pay. For quitting the vessel without leave before she is placed in security, he is to lose not more than one month's pay. For willful disobedience to any lawful command at sea, he may be placed in irons until such disobedience shall cease, and on arrival in port, he is to lose not more than four days' pay. And so the curtailment of discipline goes all through the bill, with the result that no penalty is provided for assaulting any of the officers except the captain or mate.

Another requirement is that the seaman is to be paid one half the wages due to him at every port where the vessel shall load, etc. To this it is objected by the owners that such procedure has a tendency to impair the efficiency of the seaman, who spends his money freely when he reaches shore, and that it thereby encourages him to desert and squander his earnings as fast as they accumulate.

The bill proposes to place in the hands of the crew alone the power to force at any time the creation of a commission from among the seamen to inquire into the condition of the ship. That this is unwise from the standpoint of safety is shown by the fact that such a complaint can be brought forward at any time and without any foundation, merely as gratification of personal spite or as a threat to secure the enforcement of demands. If any such stipulation is made, the commission should include at least one of the officers.

Another stipulation, to the effect that 75 per cent of the crew must be able to understand any order given by the officers, is aimed directly against the employment of Asiatic crews, and if it be enforced, it will drive the few American ships that are now plying on the Pacific coast out of business, and will discourage ships of foreign powers from visiting American ports.

The most impracticable clause of the bill, however, is that which in addition to calling for sufficient lifeboats (liferafts are not allowed) to accommodate every one on board, demands that there shall be two able seamen for every lifeboat, by "able seaman" meaning one who has seen three years on deck at sea or on the Great Lakes. This would mean the employment of a large number of deckhands who would be idle most of their time and would see practically no active service aboard ship, except in rare cases of emergency. How pernicious is this requirement will be seen, when it is understood that the firemen, stewards, storekeepers and other members of the crew, who form the greater part of the personnel on board a modern steamer, will be excluded by law from lifeboat service.

Could anything be more fatuous? As matters now stand, some of the finest boat crews are to be found among the firemen and stewards. Capt. Rostron, who was instrumental in rescuing the "Titanic" survivors, stated recently to a member of our editorial staff that it was not an uncommon thing for a boat manned by stewards to win in the boat-racing competitions, and that the stewards of a certain ship hold a silver cup won in competition against seamen.

There are many clauses in this bill with which we are heartily in sympathy, such for instance as those which provide for each member of the crew a certain amount of cubical space, a separate berth, and living accommodations that are properly lighted, heated and ventilated; those which provide for an adequate and specified supply of good food, and sufficient drinking and bathing water; but it is most sincerely to be hoped that the committee in the House of Representatives will so far amend this bill as to eliminate all those provisions which tend to relax discipline, encourage desertion, and place unnecessary burdens upon our already depleted and rapidly declining Merchant Marine.

Descents into the Crater of Vesuvius

PROF. MALLADRA of the Royal Vesuvian Observatory, whose first descent into the crater of Vesuvius was described in the SCIENTIFIC AMERICAN of June 15th, 1912, has since twice repeated his dangerous feat, viz., on September 9th and October 23rd, 1913. The former of the two recent descents, according to a note in the *Geographische Zeitschrift*, was made for the purpose of examining a new funnel-shaped vent, over 500 feet in diameter and 230 feet deep, which appeared in the floor of the crater on May 10th. Streams of gas flow from this vent, and since last July it has also glowed with incandescent lava.

Accompanied by Prof. Storts and Paul Jacobi of Munich, Malladra first descended the southeast wall of the main crater, a climb of an hour and a half. The floor, lying nearly a thousand feet below the rim of the crater, is a broad level surface, strewn with blocks of lava, and containing numerous fumaroles. The party then made the perilous descent into the new vent, where they remained for an hour, in spite of the terrific heat and stifling gases; taking photographs, making measurements, and collecting specimens of ejected material. An examination of the last showed that the volcano has entered a so-called "Hawaiian stage"; i. e., it is ejecting liquid lava of very high temperature. Attempts to measure the temperature of the lava with thermometric apparatus suspended by a wire rope failed, the thermometer and part of the rope being engulfed in the lava. The remnant of the rope was found to be strongly oxidized. In the fumaroles of the main crater temperatures of 380 deg. Cent. were measured. The whole time spent in the crater was 8 hours.

On December 21st, Mr. Frederick Burlingham, accompanied by two Italian assistants, descended into the crater and made a series of cinematograph pictures, which have since been exhibited in London. These include views of the crater floor, of the rim of the new vent, and, finally, remarkable pictures taken at the bottom of the vent, where the party remained for 20 minutes. The pool of boiling lava, known as "Hell Pit," was photographed at close range. Danger from falling rocks and poisonous fumes, as well as the intense heat both of the air and of the rocks over which the party had to climb, make this one of the notable feats in the history of moving picture photography, comparable to the cinematographic record of an ascent of the Matterhorn secured through Mr. Burlingham's efforts last year.

The Growth of the Lake Survey

THE Lake Survey is described at length in the last report of the Chief of Engineers, United States Army. As early as 1816 local surveys of the Great Lakes were made by engineer officers, but the "Lake Survey" (known officially as the Survey of the Northern and Northwestern Lakes) as a systematic work was inaugurated in 1841. The field work has continued ever since except during the years 1882-1889, while there has been no cessation at any time in the correction, printing, sale and issue of charts. The sundry civil act of March 4th, 1911, provided that the work of the survey be extended to include the lakes and other navigable waters embraced in the navigation system of the "New York canals," and the act of June 23rd, 1913, further extended the work to include Lake Champlain. During the seventy-two years of its existence the survey has cost the Government nearly $5,000,000. The water area charted is about 95,000 square miles, of which about two thirds is on the American side of the international boundary. The shore line amounts to 8,345 miles, of which about 4,700 miles is on the American side. These figures become more significant when it is added that the total shore line of the Atlantic, Pacific, and Gulf coasts of the United States, excluding Alaska and all islands, is only 5,705 miles. The fact that about 95 per cent of the commerce on the lakes is under the American flag explains the inclusion of Canadian waters and shores in the American survey. The present series of photo-lithographed charts in colors dates from 1895. In 1913 the charts in force numbered 120, and the total number of copies issued since the beginning of the work had reached nearly half a million. Prior to 1890 one full set of charts was issued free to each United States registered vessel, but since that time all charts have been sold at a price covering only the cost of paper and printing. Annual bulletins and supplements contain information too voluminous to be included on the charts. The main office of this important service, which is one of the striking examples of the many essentially humanitarian activities carried on by our War Department, is at Detroit.

Engineering

Naval Radio-Station in San Diego.—The board of naval officers which has been investigating the site for the location of a high-power radio-station on the California coast, has selected a site on La Chollas Heights, about four miles east of the city limits of San Diego, and eleven miles from the Pacific coast. It embraces some 74 acres which lie at an elevation of 450 feet above sea level.

To Prevent Settlement of St. Paul's Cathedral.—A Mr. Miller has submitted to *The Builder* a suggestion for preventing further settlement of St. Paul's Cathredal. He believes the settlement is due to the drying out of the subsoil, and he proposes to remedy this by sinking a cofferdam wall entirely around the cathedral to a sufficient depth, and then by means of perforated water piping giving the inclosed area sufficient saturation to bring it up to its original consistency and bearing power.

Naval Officers to Study at War College.—Henceforth naval officers are to be ordered to the War College for a course of twelve months study. This marks a new era in the administration of the college. Each new class will be associated with a class that has had six months' experience, thus handing down the spirit and traditions of the college from class to class. In our opinion, the instruction here received will exceed in importance that which these same officers received years ago at Annapolis.

One Million Dollars Saved on Projectiles.—There has been a remarkable drop in the prices asked for projectiles by the various American manufacturers. Thus, the Crucible Steel Company of America asks $378,000 for 1,200 fourteen-inch armor-piercing projectiles. Last year's price for an order of this kind would have been $600,000. For 2,400 fourteen-inch projectiles, the Bethlehem Steel Company has cut its price from $1,200,000 in 1912 to $768,000 in 1913. The total saving on this year's order for projectiles is over one million dollars.

Suggestion for Saving Submarines.—A correspondent has furnished us with a description of his plans for saving the crew of a submarine that has sunk. It consists of an annular tank carried in a depression around the hatch of the submarine, to which is connected a coil of air hose. The tank can be released from the inside of the submarine, when it will rise to the surface and provide a means of supplying air to the crew and even of forcing down sufficient air to expel the water in case of damage to the hull, thereby enabling the submarine to be floated to the surface.

The Toll of the Sea.—In spite of better construction, more accurate charts and the continued improvement of lighthouse service, the sea continues to take an enormous annual toll in property and lives of those that traverse its surface. The marine disasters of 1913 amounted in money value to $35,000,000 in British-insured ships and cargoes that were totally lost. On the Great Lakes alone, the storm of last November rolled up a loss of $4,700,000. The above figures do not include damages to ships and cargoes that were not total losses; for these, the damages amount to over $30,000,000.

Weight of Locomotive "Puffing Billy."—The Board of Education, South Kensington Museum, London, has kindly furnished the following additional particulars regarding the celebrated locomotive "Puffing Billy," whose centenary occurred last year. The weight of the engine in working order was 8 tons 6 hundredweight, and of the tender 4 tons 6 hundredweight, making a total weight of engine and tender in working order of 12 tons 12 hundredweight. At a speed of five miles an hour, "Puffing Billy" was able to haul about 50 tons, but on occasions as much as 70 tons was hauled at a reduced speed.

Emergency Rudder to Avoid Collision.—We have received from Mr. George E. Bell of Cambridge, Mass., a sketch of a design for rudders to be used in the event of a threatened collision. It consists of two rudders, attached one on each side of the ship just below the water line, which normally lie flush with the side of the ship, and are provided with operating mechanism controlled from the bridge, whereby one or other can be thrown out to produce a powerful turning effect upon the ship. The controlling gear is such that the rudder can be moved out gradually through its maximum arc of turning, and sudden violent wrenching effects upon the rudder or its attachments to the ship prevented.

Another "Tallest" Building.—Plans have recently been filed with the Bureau of Buildings, this city, for an office building which, on its completion, will be the tallest in the world, reaching a maximum height of 894 feet 6 inches. The structure is proposed to be built on the block bounded by Broadway, Eighth Avenue, 57th and 58th streets. It will be fifty-one stories high, with basement and sub-basement. The façade will be of brick and light stone, and the design will be ornamental, following broadly the Gothic style. The building is to be built by the Pan-American State Association and the tower is to be surmounted by an allegorical figure representing the Association. The estimated cost is $12,500,000.

Electricity

Low-priced Electric Automobile.—It has been reliably reported that Mr. Henry Ford, manufacturer of the well-known low-priced gasoline automobile, is soon to enter the electric field, producing an electric automobile that may sell as low as $600. According to the plans that have been given out, the car will weigh 1,100 pounds, of which 405 pounds will be taken up by the storage battery equipment. The storage battery will be of the Edison nickel-iron type and the machine will have a radius of 100 miles per charge.

Electric Operation of Turret Guns.—The recent announcement that the British dreadnought "Invincible" is to have its gun-controlling mechanism changed from electric to hydraulic gear has met with much criticism among electrical engineers in Great Britain. It is claimed that the change signifies no superiority of the hydraulic system, but is due chiefly to friction between two departments, one of which controls the guns and the other the electrical equipment. In our own navy, the guns are operated by electric motors under control of hydraulic variable speed gears.

Heating Churches by Electricity.—Electric power companies are constantly searching for outlets for their power during the off-peak load period. *The Electrical Review and Western Electrician* suggests that the heating of churches comes under this class. In some parts of Switzerland and in Germany, churches are electrically heated, and recently a church in Christiania, Norway, has been fitted with an electric heating system, current being supplied at the exceedingly low rate of 0.8 cent per kilowatt hour. In this country it would probably be impossible, and certainly unnecessary, to furnish the power at so low a rate. Nevertheless, current could be supplied to the churches with profit at far below the customary rate in order to raise the output of electricity during the off-peak hours.

The Electric Mail Wagons recently adopted by the Vienna postal authorities, says the *Electrician* (London), have been subjected to a test of 312,500 car miles, lasting over 15 months. At the conclusion of this test, 45 vans of 2½ tons capacity were placed in service. Lead batteries of 42 cells are used having a capacity of 300 ampere-hours at a 5-hour rate, and a maximum charging rate of 60 amperes. The weight of these batteries is 18 hundredweight, with a normal range of 35 kilometers (22 miles) fully loaded. The motors used have a maximum output of 15 horse-power, are series wound and are housed in the wheels. The garage is partitioned for each vehicle, and provided in its basement with charging equipment. For handling the batteries an elevator rises beneath the vans, so that the discharged batteries may be unshipped and replaced by fully charged ones. The weight of each van fully loaded is 6,300 kilogrammes (6½ tons).

John Walker Wilkins, a pioneer of telegraphy in England, and the first man in the world to transmit telegraphic signals through space, died at Kingston-on-Thames on December 18th last, at the age of 86. When Mr. Wilkins was only 18 years of age, he was appointed superintendent of the Northampton and Petersborough telegraphs. And a few months later, he became the general superintendent of the lines that had been extended from Hull to Fleetwood and from Rugby to Newcastle. It was at this time that he experimented with induction telegraphy and succeeded in sending messages from one wire to another 120 feet away. To be sure, his system had nothing to do with wireless telegraphy, as we now know it, in which Hertzian waves are employed. Nevertheless, it does mark the first attempt at space telegraphy. Unfortunately, Mr. Wilkins dropped his work in telegraphy shortly after visiting this country in 1851, and took up engineering work instead.

Automatic Isolated Lighting Plant.—A new automatic charging panel has recently been put upon the market for use with isolated storage battery plants. It is arranged to deliver the charge through the battery at a tapering rate, heavy at the start and gradually diminishing to a low rate at the finish, so as to avoid overheating, injurious gassing or spraying, and injury to the battery's plate. At the same time, a practically constant voltage is maintained on the external circuit during charging, so as not to disturb the lighting system. The entire operation is completely automatic, the gas engine stopping and disconnecting the dynamo and connecting the lamp circuit direct to the battery when the charge is completed. The only non-automatic feature, and this is intentionally retained, is that the system must be started by hand when it is time to re-charge, but warning of this time is given by a red lamp or an electric bell alarm. The reason the starting is not rendered automatic is because it is considered essential that the operator go in person to the plant and make sure that the engine is properly oiled and supplied with the requisite gasoline before it is started. To start the system, it is merely necessary to throw a switch when the battery current, acting upon the dynamo as a motor, cranks the engine until it runs of its own power.

Science

An Investigation of the Spanish Dialects of Mexico has been undertaken by Dr. Rudolf Wagner, who will also collect folklore from both the Indian and the Spanish-speaking populations of that country.

The Audubon Societies expended $80,000 in bird protection in this country last year. Junior Audubon classes, organized under the direction of the National Association of Audubon Societies, have attained a membership of 52,000.

Benjamin Osgood Peirce, Hollis Professor of Mathematics and Natural Philosophy in Harvard College, died recently in Cambridge, Mass. He was born at Beverly, Mass., February 11, 1854, and was a son of Benjamin Osgood Peirce. He received the degree of A. B. at Harvard in 1876; Ph.D. at the University of Leipzig. From 1879 to 1880 he was a student in Berlin. In 1881 he became instructor in mathematics; Assistant Professor of Mathematics and Physics, 1884 to 1888, when he became Hollis Professor at Harvard. Prof. Peirce was the author of "Theory of the Newtonian Potential Function," "Table of Integrals," and "Experiments in Magnetism."

The Big Game of British East Africa, outside of the three preserves of the colony, is rapidly vanishing, and, according to W. T. Hornaday, "is absolutely certain to disappear in about one fourth the time that it took South Africa to accomplish the same result." Hornaday points out that the present legal bag limit is ruinously extravagant; for $250 any man may buy the right to kill 300 head of hoofed and horned animals of 44 species, not counting carnivorous animals that may also be killed. Thus the richest big-game fauna of any one spot in the world, which nature has been several million years in developing and placing there, seems likely to be wiped out by man within the next fifteen years.

Medical Education in the United States.—In an interesting report on this subject by Dr. Graham Lusk, published in *Science*, it is stated that in spite of the campaign for higher standards waged by the Council on Medical Education of the American Medical Association and other agencies, there are still four States in which it is not necessary that an applicant for medical license be a graduate of a reputable medical college, while in the year 1912 the authorities of Tennessee presented the spectacle of licensing 175 persons who were not graduates of any medical school whatever. As to the medical schools themselves, however, it is gratifying to learn that quality has improved at the expense of quantity. The number of schools in this country has diminished from 166 to 110 since 1904.

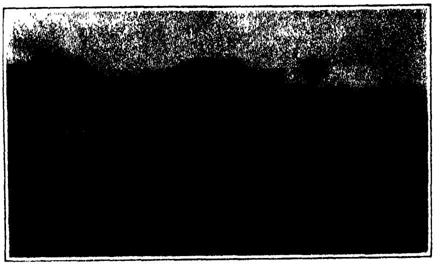
The Sea Route to Arctic Siberia.—The commercial possibilities of the route from Europe to the Arctic coast of Siberia *via* Kara Sea were again signally demonstrated last season, when the steamer "Correct," commanded by an Englishman, and having on board Dr. Fridtjof Nansen and two Russian officials, accomplished the voyage to the Yenisei and return, carrying profitable cargoes both ways. The voyage from Tromsö, Norway, to the Yenisei took 22 days, but the return between the same points was made in 10 days. A lecture on this voyage and the lessons it teaches will be delivered by Dr Nansen before the Imperial Russian Geographical Society, at St Petersburg. When it is remembered that the Yenisei River is one of the greatest natural highways of Asia (it is navigable for 1,840 miles from its mouth), and drains a region of immense mineral wealth, the importance of the fact that for about two months in the year navigation between its mouth and the ports of Europe is possible, will be evident.

The "Vinerie" System is one of several recent developments of wine-making described in a valuable paper by Messrs. F. de Castella and W. P. Wilkinson presented at the last meeting of the Australasian Association for the Advancement of Science. It consists in the sterilization of the grapes, as soon as they are vintaged and crushed, with a dose of sulphurous acid to render fermentation impossible. They can then be stored until such time as suits the wine-maker and fermented at leisure, after the removal of the sulphurous acid by the operation known as "desulphiting," under most suitable conditions as to temperature and cellar care. Thus wine-making is put on somewhat the same footing as brewing; i. e., the raw material may be harvested as rapidly as desired, but its transformation into wine is carried out as deliberately as the manufacture of beer. Evenness of type and reduction in the cost of handling are some of the advantages of this process. Desulphiting is performed in a column analogous to the rectifying column of a still, in which the bubbling of air through the liquid, under reduced pressure and at a temperature of about 70 deg. Cent. (158 deg. Fahr.) removes practically the whole of the sulphurous acid. Several important "vineries" have been established in Europe and Algeria, and it is expected that the use of the new process will be enormously extended within the next few years. One of its promising applications is in the manufacture of unfermented grape juice. The main credit for this innovation in wine-making is due to Barbet, the well-known authority on distillery equipment.

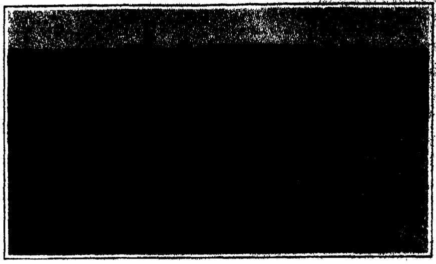
The Licorice Trade of Syria

The Curious Story of a Plant that is a Useless Weed in its Own Country and a Valuable Herb Abroad

By John D. Whiting



Factory and warehouse at Alexandretta where licorice root is pressed.



A great pile of licorice root at Aleppo.

WHERE and how is licorice obtained? What are the proportions of the trade that produces it?

A very considerable part of the licorice root used in America is from marshy plains in Turkey and Russia

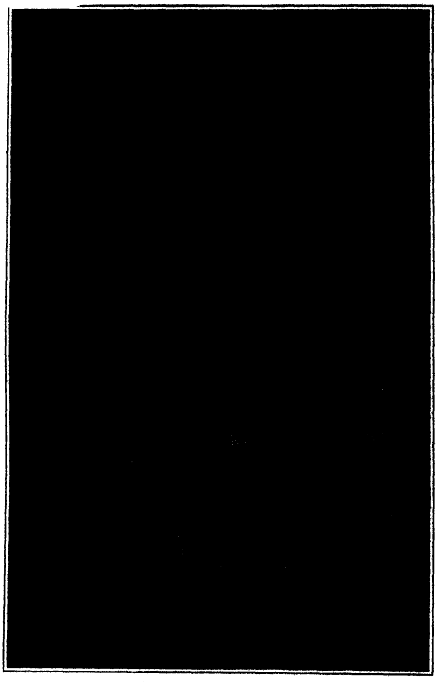
This root is not cultivated, but grows wild in large quantities, generally in great stretches of open ground where the soil is more or less damp It is regarded as a serious pest and greatly interferes with cultivation Much land is abandoned to it, while some is plowed and sown notwithstanding its presence. It is a perennial herb of the genus *Glycyrrhiza* of the bean family. The licorice of commerce is obtained by evaporating an infusion of the sliced roots This solidified substance is used for flavoring confectionery and beer as well as entering into the make-up of most of the brands of tobacco.

The growth above ground of the plant is about two feet, while the root is about as deep beneath the soil. The land in Syria from which the root is gathered is leased from the owners, the condition, as far as lands that are cultivated, being that the digging out of the licorice root must cease when the time comes for planting the cereal crops. The result is, as far as these lands are concerned, that the getting out of the roots must be done quickly as soon as the rains, which begin in October generally, have somewhat moistened the ground, as it would be very difficult to do the digging in the long dry summer

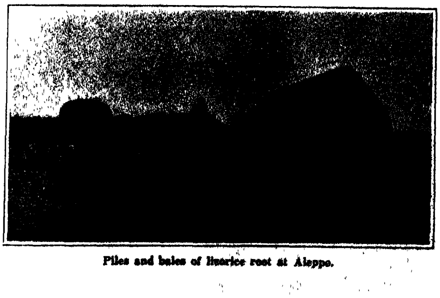
The collecting stations of Syria are at Antioch, Aleppo, Bagdad and Damascus. The company mentioned has other stations in the Smyrna district as well as in parts of Russia. Around the main stations are smaller depots located in the midst of the fields, each in charge of a man whose duty is to receive and guard the licorice as brought in by the natives These latter dig out the root with the primitive picks such as were doubtless used from the time of Abraham, and carry it on donkeys and otherwise as they can to the local station where it is weighed, as the payment is according to the quantity by weight, and they receive a receipt for the amount delivered. Traveling cashiers mounted on horses make the rounds of the depots, collecting and paying for the receipts

The root is piled in great stacks, and when the digging season is over a watchman takes charge, and the root remains thus stacked through the winter and the following summer, when it becomes quite dry and is ready for transportation to the coast. Great care has to be exercised that the stacks do not heat or mildew

One of the greatest questions involved is that of transportation. All the root from Aleppo and Antioch has to be carried to the seaport of Alexandretta. The largest contractors are Bedouin from near Hama. These receive large sums in advance to enable them to buy camels, and it is said by the members of the firm conducting the business, that these Bedouin are always faithful in carrying out their contracts. The root is packed into huge bags, two of which form a camel load. The transportation is also paid for by weight, and the weight is carefully checked when finally delivered. These Bedouin are found to be quite honest and faithfully deliver the quantity of root intrusted to them; but in their eyes the root is of little or no value, and they have no compunctions about making a little fire of the dry roots with which to bake a loaf of bread. This is the point that has to be guarded in the matter of weight.



Warehouse and hydraulic press for licorice root at Alexandretta.



Piles and bales of licorice root at Aleppo.

At the port of Alexandretta are several large presses which are located on the seashore.

Here, as our illustration shows, are seen immense stacks of the licorice. For shipment it is pressed into convenient sized bales by hydraulic presses, a couple of bands of strap iron being sufficient to hold one of the tightly compressed bales together. The bales are stored in large warehouses until shipped.

The Aleppo district gathers and exports on an average an aggregate of 8,000 tons annually of dry licorice root, while Bagdad yields about 6,000 tons, Antioch 4,000 tons, and Damascus 500 tons. All these stations are worked by the company itself except Damascus, whence it is supplied to them by native contractors. At Alexandretta one press is owned and operated by a native firm, but they sell their entire output on the ground to the American company mentioned.

At Smyrna a small quantity of the root is extracted for the European trade, and all the rest of this great annual harvest of root is shipped in a raw state to the United States.

This industry is a great blessing to this comparatively poor region, employing as it does many hundreds of natives and bringing cash into the country instead of taking it out, as so many foreign enterprises do.

The process by which the licorice is extracted from the root has already been spoken of, and it is interesting to add that after that is completed the pulp is pressed, with American ingenuity, into boards which are used in cabinet work and which are said to make up into novel and handsome articles.

Radiotelegraphy in Siberia.—The remote corners of the Russian Empire are rapidly being connected up with the world by wireless. During the year 1914 it is intended to install stations at Markovo, on the Anadyr River; Sredne-Kolymsk, on the Kolyma River; Tigil, Kamchatka; and Alexandrovsk, Sakhalin.

Foolproofing the Motor Truck

Eliminating the Personal Element in the Operation of the Commercial Vehicle

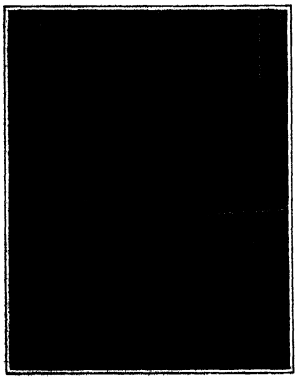
By S. H. Whiting

ALTHOUGH the motor truck has already reached the stage of perfection attained some time ago by the pleasure car, the designer of the former is confronted with far more serious problems than are to be found in the construction of automobiles of the runabout or touring type. The reason for this difference is not difficult to find. The business man purchasing a pleasure car looks upon his investment as more or less of a luxury and charges it to recreation and enjoyment. The motor truck, on the other hand, is purely a business proposition, and as such, must prove its ability to bring a greater return on the investment than can the horse system which it replaces. The result of this condition is that the pleasure car receives better care and is handled by more competent persons than is the truck. A $25 or $30 a week chauffeur is hired to drive and care for the pleasure car, or the owner gives it his personal attention. This salary for a truck driver, on the other hand, would be considered to be rank extravagance, and the tendency is to break in horse drivers as truck operators at a very slight increase in the $12 or $14 wages that they may have been receiving previously.

Naturally the truck manufacturers have had to consider these conditions, and the fact that the personal element has received deep thought is evidenced by the "foolproof" constructions and devices now found on many commercial vehicles. It is not to be expected that automatic steering and stopping devices will be installed, for every driver is supposed to possess the average amount of human intelligence, but the operation of interacting mechanical movements has been so designed that the manipulation of a lever at the improper time or in the wrong direction can do no more than to stall the motor. This effect, in part, is obtained by constructing shafts, joints, and bearings of sufficient strength to withstand any strain to which they can possibly be subjected, but this is supplemented by design of a finer order that materially reduces the probability of imparting such strains to the parts in question.

The design of clutches and transmission systems is illustrative of this point. Disk clutches or those of the cone type with cork inserts or small springs placed under the leather serve to prevent the sudden application of power to the rear driving mechanism—even though the driver's foot may slip from the clutch pedal or he may willfully release the pressure too quickly. The application of the load may be sufficiently sudden to stall the motor, but the owner may rest assured that there is no danger of a broken gear tooth or a sheared shaft key. The friction surfaces of the clutches, which are subjected to a greater amount of wear than any other portion of the car, are especially designed for such "punishment," and many instances can be cited in which trucks have been given hard usage for sixty and seventy thousand miles without the renewal of a clutch surface.

The planetary transmission has long been noted for its "foolproof" qualities, for the fact that all of the gears are in mesh all of the time precludes the possibility of stripped teeth when the change from one speed ratio to another is made suddenly without releasing the clutch. The limitations of the planetary transmission, however, to those of the two-speed type, has caused their gradual disappearance from use on heavy trucks, and to-day we find the three- and four-speed sliding gear transmissions occupying the center of the stage. These are of the same type as are used on pleasure cars, but their wide faces and general heavy construction make them better adapted to transmitting power to the greater loads at the rear wheels. While these gears are made of special steels and are subjected to special heat-treatment, all manufacturers do not think that this is sufficient protection against stripping or chipping when a careless or ignorant driver attempts to change speeds without first disengaging the clutch, and accordingly several devices to prevent this clashing of gears are in use on several makes of trucks. Probably the simplest of such devices is one in which the transmission lever is automatically locked whenever the clutch is engaged. The gears, therefore, cannot be shifted until the clutch pedal is depressed. This mechanism consists of a quadrant that is swung by the transmission lever. In the periphery of this quadrant are cut notches corresponding to the position of the transmission lever when set at the various speeds, and by means of a latch released by the clutch pedal when the latter is depressed, the transmission lever is locked except when conditions are proper for the gear change. Other "safety" systems consist of an individual disk clutch for each gear ratio, and the "dog clutch" and spring type. In the former, the gears are in mesh at all times, although they are mounted upon the main shaft and countershaft in the same manner as in the sliding gear transmission. It is the clutches that are operated to obtain the various gear ratios, however, and these are so arranged that but one can be engaged at a time. In the other type of transmission mentioned above, a small handle located under the steering wheel is used to apply spring tension to the gear that it is desired to shift, but by means of an ingenious arrangement of cams and dog clutches, this gear is prevented from moving until the clutch is released.



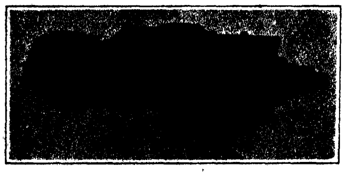
Spark lever inconveniently located to prevent tampering.

While these types of transmissions are not necessarily in general use, they are mentioned as examples of the thought that has been put upon "foolproof" design in order to eliminate, as far as possible, that uncertain personal equation that always enters into the success or failure of a motor truck installation.

But while considerable time and thought have been put upon the transmissions and "running gears" of trucks, the problem here is only one of mechanical strength. The motor, however, is susceptible to a variety of conditions that affect its efficiency, length of satisfactory service, and power output. It is well known by every motorist, for example, that to obtain the best results from his engine, the spark lever should not necessarily be operated *only* in conjunction with the throttle, but that the speed at which the engine is operating should have an important bearing on the time at which the spark should occur. But to obtain that proper position in which throttle opening and engine speed are taken into consideration, the driver must have had considerable experience, and must "know" his motor thoroughly. In fact, it is better that the spark should be left in a fixed position than that it should be unduly advanced at slow motor speeds or fully retarded at wide open throttle. Because of the difficulty of obtaining truck chauffeurs who will pay proper attention to these important details of motor operation, some of the truck companies produce machines on which no spark lever is provided, the contention being that if the spark is set to occur at the top of the stroke, no harm can be done, and the loss in efficiency that would be entailed at high speeds is negligible when compared with the damage that might ensue through improper operation of the spark.

On other trucks, the makers have not taken quite so radical a step, but have assumed that some sort of spark control is advisable. They have consequently located the spark control lever on the dash board where it may be reached if the driver leans forward, the theory being that, if it is not placed close at hand on the steering wheel, the spark will not be advanced or retarded unnecessarily. But this desire to remove the spark control lever from the possibility of interference by incompetent hands has resulted in the development of magnetos provided with automatic spark regulation in which the ignition in each cylinder is controlled to occur in accordance with the speed at which the engine is running.

It is generally admitted that the two conditions of operation which do more to injure a motor truck than any other practices are overloading and speeding. Unfortunately, no practical device has as yet been developed that will automatically prevent the former evil, but efficient governors have been devised that effectively regulate the speed of the motor. These are either of the centrifugal or hydraulic type, and generally operate on the throttle. They are so arranged that their operation or adjustment cannot be interfered with by an unprincipled driver without ruining the entire mechanism. Such a device not only controls the rate of travel of the truck, but regulates the speed of the engine and thus prevents that "racing" of the motor that is so conducive to wear and loose bearings, and yet that nevertheless seems to be the delight of many a so-called "expert" driver.



Gear ratios varied by means of clutches.

Because it is assumed that under certain conditions—such as when running under low gear, for instance—it is often advisable to increase the revolutions of the motor beyond the point at which the maximum speed on high gear would be obtained, some types of governors are placed on the transmission shaft. Such governors control only the speed of the car, but the owner of the vehicle may know that the speed at which his truck can carry its normal load efficiently, is not being exceeded by even the most careless driver.

Of course, on any mechanism subjected to the intense heat and great strains of the automobile motor, sufficient and efficient lubrication is of prime importance. An engine cannot run without fuel, but no harm to the machine itself will be incurred from a lack of gasoline. On the other hand, an engine can run for a short period without oil, but more harm may be done in this time than would result from thousands of miles of use under the proper conditions. And yet, for all its importance, the lubrication of the motor is almost the last point about which the motor truck driver need concern himself. With the unit power plants now coming into use, in which motor crank shaft and clutch—and sometimes the transmission, as well—are housed in the one aluminium crank case and extension, one lubricating system supplies the entire motor and allied parts. Oil in the proper amount is supplied to the necessary parts whenever the motor is run—and it is only necessary for the driver to fill the oil reservoir and gear cases at stated intervals. Points such as spring shackles,

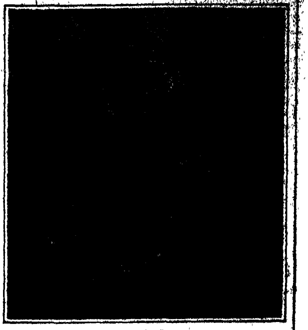
Reassembling the motor.

The Problem of the Second-hand Motor Truck

How Used Machines Are Thoroughly Overhauled and Reconstructed in the Builders' Local Service Stations

By John S. Hardwhite



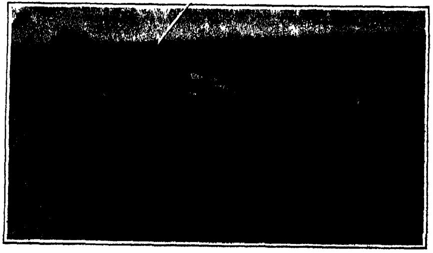
Testing the speed of the motor.

"SECOND-HAND" is a term carefully avoided by those concerns and individuals who make a business of buying and selling trucks or pleasure cars that probably have "seen better days." Whether it is thought that there is more or less ignominy attached to the purchase of a second-hand commercial vehicle that is now made in new models in such styles and at such prices as to fit the requirements and pocket book of practically every business man, or whether the term "second-hand" conveys the general meaning of "cast-off" or "discarded," matters not, but if the prospective purchaser of such a truck would be diplomatic, he should refer only to the "used" machine, or "rebuilt" truck.

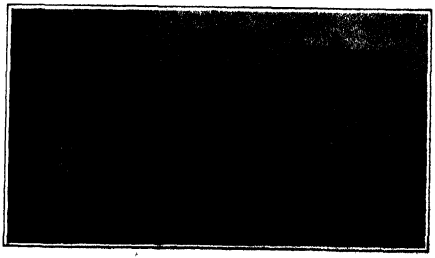
It is but natural that there should be a large number of such vehicles on the market; a man doing business in a small way may feel the need of a one-, three-, or five-ton truck, but may not have the ready cash to invest in such a machine when new; this demand is more than supplied by the number of trucks that are taken in exchange for new ones by the manufacturers, and by those that fall into the hands of the used car brokers But the pitfalls besetting the path of the unwary purchaser of a used machine are many, and the danger that the supposed bargain will become the most highly gilded of gold bricks is great. A famous name-plate may mean nothing on a second-hand car; the reputation of the manufacturer for high-class design and conscientious workmanship may count for naught; a used—or misused, rather—truck becomes a hybrid, an orphan, with no parent manufacturer to stand sponsor for it or for its performance. A truck possessing the reputation of using well-fitted and heavy bearings and of claiming more than its share of high-class and expensive steels may be absolutely ruined in a short time if it falls into the hands of an ignorant or careless driver or owner; while a truck boasting only a mediocre reputation when new, may, by proper handling and frequent inspection and repairs, be worth double the price of the first truck that had been so sadly misused.

Therefore it behooves the prospective purchaser who is a firm friend of a car or truck of a certain make to pick his way carefully before he decides on a second-hand machine of the same brand. To be sure, if the truck in question is sold by the "used car department" of its original manufacturer, and if, as is usual under such conditions, it has been carefully overhauled and rebuilt, and is sold with a six months' or a year's guarantee, it may prove a most excellent bargain and profitable investment. Many reliable manufacturers take used trucks of their own make in exchange, to apply as a partial payment on the sale of a new one, while others make a fairly liberal allowance for a truck of any brand. As chickens come home to roost, so do such trucks taken in exchange, eventually reach the parent factory in which they were born. There they again pass through the hands of their builders, are rejuvenated, as it were, and become safe and substantial investments for the man who is looking for a reliable truck at a lower price than the cost of a new one. A motor truck is an assemblage of hidden parts; the vitals of the machine are covered from the eye; several hours of expert dismounting may be required before the condition of an important bearing can be accurately determined; and the entire machine must be thoroughly overhauled before its actual value as a transportation vehicle can be ascertained. For the prospective owner to undertake this overhauling in order to determine the actual value of the truck, is impracticable; for him to employ an expert to undertake this work would prove prohibitively expensive. Therefore it is evident that his second-hand truck should be purchased only from an individual or company that is not only competent to overhaul and repair the vehicle, but whose word and guarantee are implicitly to be relied on. There are concerns doing a legitimate business in the rebuilding and sale of second-hand trucks, but their responsibility as to its performance replaces that of the original manufacturer, and their status should therefore be thoroughly investigated.

Dismantling the motor of a second-hand car.



Investigating the rear-end construction.



The chassis rebuilt and ready for service.

It may be argued by the man experienced in the *operation or management of* motor trucks, that he can determine by the action of the vehicle, by its "feel," and by the sound of the various parts, whether it is in proper running condition or not. Such a man, however, overconfident of his own ability in this line, is the one most susceptible to trickery. "Doctoring" a badly-worn motor truck is simpler and more deceptive in its results than is "doping" a race horse. By the use of preparations of heavy grease, badly-worn gears in the transmission case and differential may be made to run as silently—for a while—as the most perfectly cut bevels and spurs of a new pleasure car; poorly-fitting pistons and rings may be concealed and made to hold compression in the cylinders for as long a time as would be required by the ordinary demonstration; loose or even burned-out bearings may be temporarily repaired by means of makeshifts; slipping clutches may be made to grip, and leaking radiators plugged to hold water. Even defective rear axles may be repaired without being replaced, the necessary part being brazed or welded on. *All of* these repairs, being but makeshifts, are temporary—very much so, in fact—but all serve to make the machine appear to be in satisfactory condition for the first thirty miles or more. Instances could be cited, for example, in which a machine ran satisfactorily for several weeks after purchase, until one day a rear wheel calmly rolled off, and it was found that the rear axle had been broken months before and that a repair had been effected by attempting to weld the pieces and endeavoring to cover the poor appearance of the job with solder or white metal that would fill the crevices.

It is expected that every truck bought directly from an irresponsible individual or concern will be found to have been treated in this manner. Some trucks are sold with the frank understanding that no overhauling, inspection, or repairs whatsoever have been done. The condition of such trucks should be investigated carefully, but the purchaser or his agent has the advantage in this case of knowing that what trouble exists will probably be manifested immediately in the operation of the machine.

It is evident from the foregoing that the value of a second-hand truck lies in the reputation and reliability of the previous owner, rather than its former connection with a factory that may have stood for all that is best in truck construction. That there are "tricks in all trades" has never been better exemplified than in the case of the second-hand truck. However, it should be remembered that it is manifestly unfair to assume that there are "tricks in all trucks."

International Conference on Safety of Life at Sea

THE International Conference on Safety of Life at Sea, which has been meeting in London, has signed the seventy-four articles in the convention.

Its main points were summarised by Lord Mersey, chairman of the Conference, as follows:

"An international service is to be established by the nations chiefly interested for the purpose of an ice patrol and ice observation as well as the destruction of derelicts in the North Atlantic. It is to be under the control of the United States. This service is to take over and continue the work done by the two vessels employed by the United States in 1912-13 in locating ice, in determining its limits to the south, the east and the west, and in keeping in touch with it as it moves southward in order that vessels may be kept informed by wireless telegraphy on its position.

"The service will also continue the ice observation work started last year by Great Britain, with the object of determining before the ice becomes a peril the fundamental conditions which govern its movement.

"The service will also continue the duty of dealing with dangerous derelicts east of a line drawn from Cape Sable to latitude 34 north, longitude 70 west. The waters to the west of this line will continue to be watched by the United States.

"The duty is also imposed on all shipmasters to report the presence of dangerous ice and derelicts, and a code has been prepared to facilitate this reporting.

"When ice is reported on or near the track a ship must proceed during the night at moderate speed or alter its course so as to clear the danger zone.

"The practice by which routes across the Atlantic are fixed by agreement between the steamship companies has been left unaltered and the governments undertake to impress all shipowners with the desirability of following as far as possible these routes.

"The effective lighting of boat decks is provided for by the convention and the carrying of Morse lamps is made compulsory.

"An international code for urgent and important signals has been adopted.

"It was impossible to revise the international collision regulations, as many States which were parties to those regulations were not represented at the Conference, but the convention binds the contracting States to bring about a revision of these regulations.

"Other points affecting the safety of navigation were found impossible of embodiment in definite articles, but the committee submitted resolutions embodying its views.

"On the question of construction of passenger steamships the convention provides that the existing arrangements shall be considered on their merits by the country to which each vessel belongs, with the view of providing increased safety where practicable and reasonable.

"The most difficult point this committee had to deal with was the division of ships into watertight compartments. The convention provides that the degree of safety should increase in a regular and continuous manner with the length of vessels, and that vessels shall be as efficiently subdivided as possible, having regard to the services for which they are intended. It is also explicitly stated that the requirements imposed by the convention are minimum requirements."

Among the most important subjects dealt with under the heading of construction Lord Mersey mentioned bulkheads for the prevention of the spread of fire, means of escape from watertight compartments, requirements as to the strength of bulkheads and decks, the reduction to the smallest number practicable of the openings in water-tight bulkheads, the restriction of the number of openings in the ship's outer skin, appliances for closing the same; requirements as to the fitting and extent of double bottoms, the periodical operation and inspection of water-tight doors, etc.

Lord Mersey referred to the compulsory entering in logs of drills and inspections and the requirements by the convention of adequate backing power and auxiliary steering apparatus.

The committee, he said, had recognised the importance of making a further study of these subjects and of the exchange of information.

The full text of the convention will be published next month, when we shall publish a complete digest.

A Radium Motor

The Possibilities of Radium as a Motive Power of the Future

By Major H. Bannerman-Phillips

THE demand for a type of motive power for ships, vehicles and aircraft which can be generated by machinery working in a circumscribed space, and which does not require large stores of fuel to be carried, and a numerous staff of engine hands, stokers, etc., has led to the invention of oil engines and internal combustion motors in recent times. This demand seems likely to be redoubled in future, while at the same time the ever-increasing consumption of coal and the products of petroleum points to the ultimate, though not perhaps imminent exhaustion of our terrestrial supply. Under these circumstances it is natural that students of matter and the general properties of matter as affected by energy or force should be called in to co-operate with the engineer and the chemist in order that fresh sources of energy may be tapped and the powers of nature persuaded to work in harness for the benefit of posterity.

It may be that radium, that rare element whose properties are being slowly revealed to the wondering comprehension of the present generation, may prove to be a source of that motive power which is so urgently sought for, and in a lecture at the Cancer Hospital in London on December 10th last, Mr. C. E. S. Phillips (F.R.S. Edin.), who is honorary physicist to the Electrical and Radio-therapeutic Department of that beneficent institution, foreshadowed ideas in this connection which may bear fruit in time to come. He pointed out that radium in solution always decomposes water in which it is placed, giving rise to an explosive mixture of gases—oxygen and hydrogen; and he proceeded to illustrate the working possibilities of such a mixture with a small apparatus of primitive nature for the benefit of his audience. Owing to the scarcity of radium, he used on this occasion other means of producing the required explosive mixture, but the audience understood that it could have been produced by the action of radium as indicated. The apparatus consisted of a flywheel in the shape of a small paper windmill with the sails going round horizontally, instead of vertically. Close to this stood a glass tube shaped like the letter Y with a short length of electric wire inserted in each of the upper arms of the letter. This represented the combustion chamber of the embryo motor of the future. Fastened to the lower end of the Y tube was another tube running to a glass bottle containing the explosive mixture of oxygen and hydrogen referred to above and supposed to have been produced from the decomposition of water by radium solution. The lecturer turned a tap which let the mixture pass from the bottle through the tube to the Y-shaped "combustion chamber," and switched on an electric current, producing sparks in the upper arms of the Y. The sparks caused a continuous series of miniature explosions of the gas mixture, and the puffs of wind which resulted therefrom acted on the arms of the paper windmill and blew it round. It was a pretty experiment and may have more behind it. If the decomposition of water is all that is required to furnish gas for a new form of explosion motor, it seems hardly necessary to use radium solution for the purpose; there are other and cheaper methods of attaining the same end, and it is well not to count upon a supply of a commodity which is certainly unattainable at present. The enormous cost of even a minute quantity of radium at the present moment places it quite outside the pale of practical mechanics, and this is not surprising when one considers that it took M. and Madame Curie two years to produce one gramme of chloride of radium, and that they "worked over" eight tons of pitchblende in the process.

The Competition for the Michelin Prize

THE Michelin prize for the aviator who has flown the greatest total distance during the year, is arousing keen interest among French aviators. Thus far the pilot Fourny stands at the head of the competitors. In twenty-two consecutive days he covered the remarkable distance of 15,989 kilometers. This performance certainly speaks well for his Renault 70 horse-power motor. For eight hours a day during this period of twenty-two days the motor made 1,800 revolutions a minute.

New Motor Service for Siberia.—It is proposed to establish an automobile mail and passenger service between the cities of Verkneudinsk and Troitskosavsk in the Province of Transbaikalia in Siberia, shortly. The length of the proposed route is approximately 215 versts (142 miles) and if the undertaking becomes a fact, combined passenger and express motor cars will make the trip once a day in either direction. The fare per passenger has been tentatively set at from 21 to 22 rubles, about $12.

The Highest Tree in the World

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of November 22nd, 1913, page 398, reference is made to the tall trees of Australia, implying that they exceeded the height of those found elsewhere. Having resided in Australia for ten years, and being fairly well acquainted with the trees there as also with the literature on the subject, it occurred to me that an explanation would not be out of place; hence, I am sending as an inclosure some extracts from Mr. Maiden's work, which is everywhere considered authoritative.

The Giant Trees of Australia.

The following is extracted from "The Forest Flora of New South Wales," by J. H. Maiden, Government botanist, page 162, in reply to the note which appeared in SCIENTIFIC AMERICAN for November 22nd, 1913, page 398, which reads as follows:

"It is claimed that some of the eucalyptus of Australia are taller than the California redwoods, which are commonly considered the highest trees in the world."

Visitors to the Melbourne International Exhibition of 1888 will remember the photographs of a large-butted gum-tree by Mr. N. J. Caire, photographer, who stated that he had come across this monster in Gippsland, and that its height was 464 feet. Here was something very definite to go upon. The trustees of the Public Library, Melbourne, voted £100, the trustees of the Exhibition Building another £100, the Minister for Lands promised a sum not exceeding £800, to have this leviathan measured and photographed. After some hesitancy on the part of the photographer, the identical tree photographed was found. The Inspector of Forests and a Government surveyor measured it accurately, and found it to be 219 feet 9 inches. Here was a come-down. "No tree in the neighborhood reached 300 feet." The Hon. James Monroe, premier of Victoria, thereupon offered a reward of £100 out of his own pocket for any Victorian tree 400 feet in height, *and the reward has remained unclaimed to this day.* Another man claimed to have found a tree there 525 feet high; but it turned out that the above mentioned tree was the one referred to. . . *Prof. Sargent is an eminent authority;* . . . and in view of the actual measurements that he presents, viz., 340 feet in height for a redwood and a girth around the trunk of 107 feet for its congener, the "Big Tree," I am of the opinion that, so far as our knowledge goes at present, California is the home both of the tallest and the broadest trees in the world. (1905.)

When the highest living Australian authority gives the banner to the United States, why should it not be accepted? FREDERIC W. GODING, *Consul General.*

Guayaquil, Ecuador.

Escape from Sunken Submarines

To the Editor of the SCIENTIFIC AMERICAN:

The inability to locate the British submarine A-7, which disappeared after a dive during the maneuvers on January 16th in Whitesand Bay on the shore of Plymouth Sound, and the consequent loss of at least eleven lives, suggests to the writer the desirability of installing on each submarine a device by which the location of a disabled and submerged boat might be readily ascertained.

It would appear to be an easy matter to construct a device similar in general shape to a torpedo, which, in case the submarine was unable to rise to the surface after diving, might be ejected from a torpedo tube. This device should be weighted in such a manner that on reaching the surface it would stand more or less upright in the water like a spar-buoy. At the top of this torpedo-buoy an oiled silk red flag might be attached in the day time, or a device for emitting a dense cloud of smoke, while at night a bright intermittent light might be displayed. To the lower end of the buoy a light cable would be attached, running back to the submerged submarine.

With such a device available it should be a simple matter, in case of accident, to discharge the torpedo-buoy, which on reaching the surface would present a readily noticeable mark to guide searching vessels to the location of the sunken boat. Once located, it would in many cases prove practicable, with the aid of divers, to attach cables to the ringbolts with which I believe all modern submarines are now supplied, and draw the submerged vessel to the surface or to shallow water, where the imprisoned crew could be released.

The writer does not profess to have kept in touch with recent inventions in connection with safety appliances on submarines, but has not seen a discussion of a device similar to that described.

Steam and sailing ship repairs in floating docks I, II, and III.

The Most Modern Shipbuilding Plant in the World

Where the Two Largest Steamships in the World Are Under Construction

THE systematic and rapid manner in which Germany has built up her navy and mercantile marine is one of the most interesting developments of the modern industrial world. No nation, with the exception perhaps of the British, has understood so well the intimate relation which exists between a national navy and a national merchant marine; and the German government has seen to it that both have received the encouragement which is necessary to an adequate and relative development. The consequence is that Germany to-day not only possesses a powerful navy, replete in all its parts and most excellently administered, but it can lay its hand in case of war upon a vast fleet of mercantile cruisers and colliers (doing daily service in its merchant marine) which stands ready at a moment's call to proceed to its appointed rendezvous to be loaded with the coal, guns, ammunition, stores, etc., which are essential to turn it into a powerful and absolutely necessary adjunct of the fighting fleet.

We in the United States have neither the ships nor the policy—thanks to our fatuous neglect to build up an adequate merchant marine.

The encouragement afforded by the government, coupled with the far-sighted and courageous policy of the capitalist and shipbuilder, has led to the establishment in Germany of several great yards, all of which are capable of turning out warships and merchant steamers of any size, speed and capacity

It was our good fortune recently to visit the foremost of these yards—that of Blohm & Voss, which is situated on the river Elbe, opposite the city of Hamburg. This firm, the heads of which are Herman Blohm and Ernst Voss, was established in 1877 The plant which they have developed covers an area of about 460,000 square meters and has a water frontage of some 3,000 meters. The shipyard has its own harbor basin, which over a considerable portion of its area, is about 45 feet in depth The first object that strikes a visitor in approaching the yard by water is the towering superstructure of the building slips—a vast construction of steel columns and overhead girders suspended beneath which is a series of tracks, carrying traveling revolving cranes, capable of handling the heaviest pieces that enter into the construction of a modern warship or ocean liner. This structure is truly colossal in its proportions, and it was easily able to accommodate such ships as the "Vaterland," which is now completing alongside the wharf adjoining the building slip, and her sister ship, which is now in course of erection on the ways. These vessels are 940 feet in length over all, 100 feet in beam, and their height is over 100 feet from the keel plate to the roof of the topmost line of cabins. Despite this great height there is ample clearance between the bottom of the overhead cranes and the top of the ship's structure.

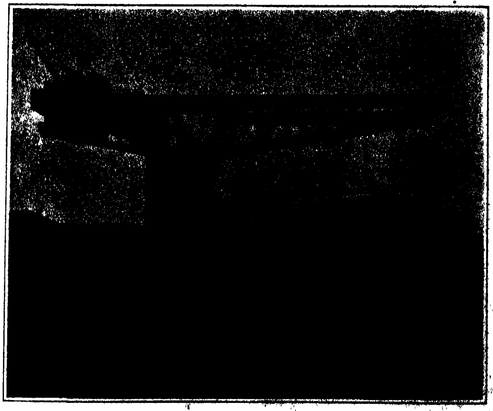
There are five older building slips located on the side of the works nearest the river Elbe, and in these ships up to six hundred feet in length can be built. The larger and more modern slips, above referred to, which face the shipyard basin, are employed in the construction of the battle-cruisers of which this firm has built so many, and merchant ships of the largest dimensions. These berths are served by no less than thirty-four cranes running on fourteen overhead tracks.

The sheets and structural shapes are heated and bent to form in extensive yards adjoining the slips, and here are found machine tools of the latest and most approved design, rolling mills, forging machines, giant shearing machines and planing and boring machines. High-speed cranes serve to transport the material rapidly from place to place.

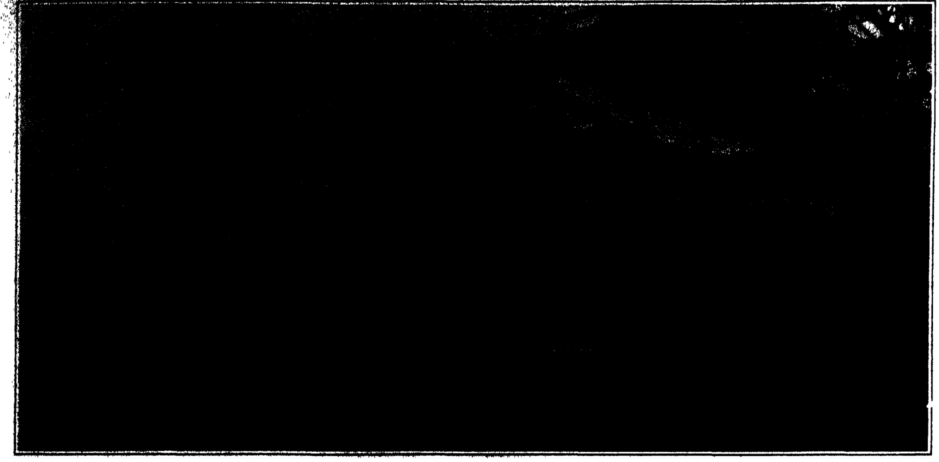
Two special shops are utilised for machining engine parts and assembling engines and turbines. One of these is devoted to reciprocating engines and auxiliary engines. The other is given up to the construction of turbines of the largest dimensions, such as those which have entered into the "Vaterland" and are being built for her sister ship. It is needless to say that special tools had to be built for handling and machining turbines of the great dimensions (they are 18 feet in diameter) of these turbines. The material is handled in these shops by high-speed electric cranes, which are specially designed for expeditious transfer from place to place. There are two separate boiler plants. The older one is devoted to the construction of cylindrical boilers such as are commonly to be found on merchant ships; the new boiler shop is given up to the building of water-tube boilers such as are usually installed on warships and high-speed passenger steamers. Special hydraulic and pneumatic machines have been designed for riveting, pressing and bending the steel sheets used in the boiler shops. Autogenous cutting and welding apparatus is extensively employed. Castings of bronze and steel are made in a special bronze and steel foundry.

Grouped around the larger shops are smaller but not less important plants, such as machine shops, carpenter shops, wood-drying and seasoning plants, a model-making shop, sawmills, paint shops and the usual auxiliary establishments of a great shipyard.

One of the most interesting objects in this yard is the huge 250-ton crane, which stands on the edge of the main basin. At present, this is the largest crane of its kind in the world. There are also a 150-ton crane, a 100-ton crane and one of



This crane, the largest of its kind in existence, can lift a load of 250 tons.



This ship, built for the Hamburg-American Line, is the largest in existence. As she went down the ways her weight was 31,000 tons, and the launch took place without a hitch She is 940 feet long, 100 feet beam, 73½ feet in plated depth, will weigh fully loaded 60,000 tons and will steam 28 knots. She differs from the "Imperator" in having a cruiser stern.

The launch of the "Vaterland" at the Blohm & Voss yard, Hamburg.

50 tons. For the transportation of material within the shipyard itself, a large number of traveling steam and electric cranes are employed. Material is extensively hauled by automobile trucks; and, of course, by locomotives running on tracks of both narrow and broad gage.

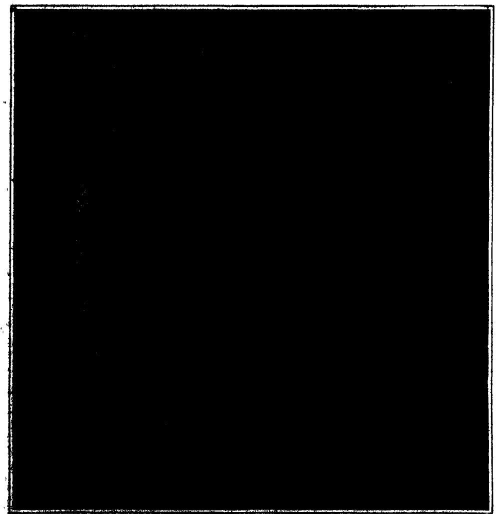
Power for operating the plant is generated in several large central stations in which reciprocating engines and turbines as well as air compressors and hydraulic pumps are installed. This energy is distributed by an extensive electric, hydraulic and pneumatic system over the entire yard. In addition to the power plants there are also gas plants for generating oxygen, hydrogen, acetylene and water gas. The oxygen, hydrogen and acetylene are employed in cutting and welding; the water gas is used chiefly for heating purposes.

The yard possesses a very fine laboratory and testing plant, both of which are equipped with modern instruments of precision for carrying out physical, microscopic and chemical investigations.

A characteristic feature of large German commercial establishments of this kind is the great attention which they pay to the design of their office buildings, which are often, as in this case, examples of very careful and highly artistic architectural planning and design. In the case of the Blohm & Voss yard, the technical and administrative staff is housed in a five-story structure of very appropriate design. The total number of officials and workmen employed at the present time is about 11,000.

As is well known, this yard has taken a prominent part in the building of war vessels for the imperial German navy; in fact, all the successful German turbine-driven battle-cruisers such as the "Von der Tann," "Moltke," "Goeben," and "Seydlitz" were built by Blohm & Voss; and they now have under construction a large battle-cruiser in which they are installing turbines of 100,000 horse-power, which are expected to give to the vessel a speed of 30 knots, if not more. In addition to the "Vaterland" and her sister, both of which are turbine-driven, the firm is building for the South American Line in the Hamburg-American Company, a triple-screw steamer which is driven by a combination of two reciprocating engines and one turbine. They are also building large docks for the Imperial German and the Imperial Austrian Navy.

A feature of the yard is the large dockage capacity, and especially the floating docks, the capacity of the five docks being 88,200 tons. This is the largest privately owned dockage in Germany, and the firm possesses the only floating dock capable of lifting the "Imperator."



Casing, 18 feet in diameter, of one of the low-pressure turbines of the "Imperator."

The Chestnut Blight

A PRELIMINARY report of the Pennsylvania Chestnut Tree Blight Commission now being distributed gives an interesting summary of the work done under its direction in the effort to combat and eradicate the destructive chestnut tree blight.

The introductory refers to the possibility of a serious timber famine confronting the American people, and the absolute necessity for concerted action of the friends of forestry and forest conservation to avert a threatened crisis. Attention is called to the fact that it costs fully one third more to-day to buy hemlock and other common varieties of building lumber than the same material would have cost only five years ago.

The chestnut blight occasioned a loss of many millions of dollars to the timber owners of Pennsylvania, and since the commission decided to discontinue its operations on account of not having received a sufficient appropriation, especial interest has been aroused, as the total extermination of our native chestnut is threatened. At least a dozen other States continue the warfare against the disease. The Bureau of Plant Industry of the United States Department of Agriculture, co-operated in a practical manner through a large pathological force. The main laboratories are at the University of Pennsylvania.

The reports of the several executive officers and others indicate very clearly that much progress has been made in the study of the proper treatment of infected chestnut trees. Especial attention was devoted to the utilization feature, and in this manner the owner of blighted timber was able to secure a ready market for its disposal at fair prices. The educational work enabled owners of trees to recognize the disease, and to obtain needful information of much value without cost, as to the treatment of diseased trees. The blight has been eradicated from the western part of the State, but spot infections will most likely reappear. Unless timber owners watch carefully, and destroy such infections promptly, the blight will spread rapidly and further heavy losses will inevitably follow. In eastern and southern Pennsylvania a large percentage of the chestnut was badly infected before the commission was created by legislative enactment.

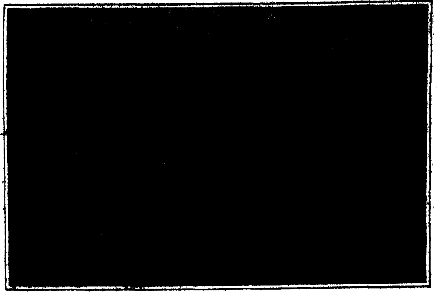
Recent cablegrams prove that the chestnut blight is prevalent in China, and therefore, probably of foreign origin Hence there is greater hope now that continued scientific research work such as is now in progress in this country, will reveal the much needed remedial measures to prevent the threatened total extermination of our native American chestnut trees.

The report contains seventy maps and engravings, and is worthy of careful preservation, as the literature upon this tree pest is limited, although the subject is an all important one from an economic standpoint. As a destructive parasitic fungus, the chestnut tree blight has done incalculable damage. It is a matter of deep and sincere regret and a direct loss to the State that no larger appropriation was granted by the Legislature.

A Good Grade of Excelsior is being made from fire-killed Alpine fir and Engelmann spruce in Colorado.

Automatically Reversed Trolley

AT the main station of the Pacific Electric Railway, from which all of the three-car interurban trains enter and leave Los Angeles, the danger to conductors as well as time lost in reversing the trolley has been done away with by an automatic system The grooves overhead in the station are arranged in a Y shape. The incoming car is reversed and this causes the trolley pole to run off laterally on one arm of the Y until it comes to the junction with the other arm. Then continued motion of the car drags the trolley back to the main line on the second arm of the Y. In this way the trolley is reversed without any delay; and as it is not necessary for the conductor to swing the pole around and walk across adjoining tracks in doing so, a common source of accident is eliminated.



System of overhead switches for automatically reversing a trolley pole.

Mail Carriers on Roller Skates

THE delivery of parcel post packages by United States mail carriers equipped with roller skates is the latest scheme devised to save time in this branch of the Government service. Incidentally, it also seems destined to cut quite a figure in the saving of shoe leather for post office employees.

The idea was originated by the foreman of the check room in the Chicago post office. In the basement of the building is a clear space of over 300 feet of smooth concrete flooring, on either side of which are arranged a total of 1,400 carriers' lockers. The checking of uniforms during the rush hours taxed the force of men in charge of this work to the limit Then the plan of providing the checkers with roller skates was hit upon, with the result that the time formerly required for carrying uniforms from one end of the locker room to the other was cut to one fourth. Following this the scheme was applied to the moving of packages of mail from one part of the building to another, and finally as a means for the regular delivery of parcel post packages on the outside.

The success of the experiment was such that Postmaster Campbell of Chicago predicts the plan will soon be generally adopted in all large cities in the country.

Roller skates save time and shoe leather in the Chicago post office.

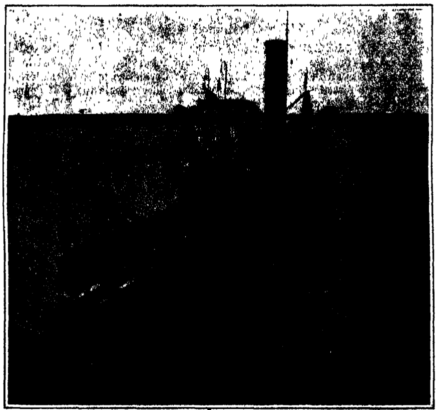
A Sea-going Dredge for China

IT would appear at first sight that in China manual labor for dredging work would be much cheaper than mechanical work, but, despite the fact that Chinese labor charges are five times lower than in Europe, mechanical appliances are proved to be much below the cost of manual labor. This difference is brought about not only by reason of the high power developed in a dredging plant, but also by reason of the fact that coal is 50 per cent cheaper in China than in Europe, and also the weather does not affect the general expenses with dredging machinery so much as human labor.

Pictured herewith is an interesting dredge recently built for the Hai-Ho Conservancy Board, Tientsin The dredge is of the barge-emptying and suction-loading type, and is capable of discharging the spoil into barges alongside, or through a floating pipe-line 1,000 feet in length, or through a shore delivery pipe-line over a distance of 9,800 feet.

The vessel is used as a suction dredge, either working at side anchors or in motion, and as a stationary pumping station for the discharge ashore of spoil out of barges. When pumping while in motion the dredger is arranged for discharge over either side into barges towed alongside, or through an opening in the bow, to which opening a floating pipe-line is fitted when dredging at side anchors. To balance the vessel the shore delivery pipe-line is fitted on the port side, while the barge suction is usually effected over the starboard side. The suction pipe for direct dredging at anchor is provided with a suction mouth, armed with a sleeve, so fitted as to avoid clogging when dredging a furrow 8 feet deep in easily collapsible earth. When the dredger is in motion the suction pipe is capable of reaching to a depth of 20 feet, and when dredging at anchor with a different suction mouth, of reaching to a depth of 25 feet. The normal service speed is approximately 8 knots.

When working as a pumping station, the dredge discharges the spoil through a 24 3/8-inch pipe-line, and delivers by means of its sand pumps 46 cubic yards of water per minute at 150 revolutions of the engine, while for the water pump the output is 47 yards with 160 revolutions of the engine. When dredging at anchor and discharging through a 1,000-foot floating pipe-line of 20-inch diameter, using one sand pump, the duty for the sand pump is 46 cubic yards per minute with 160 revolutions of the engine, while when dredging in motion and delivering into barges alongside, the output of the sand pump is 90 yards per minute at 150 revolutions of the engine.



Twin-screw barge emptying and suction loading dredge for China.

The Largest Flagpole

A CONSULAR report states that what is claimed to be the largest one-piece flagpole in the world is to be erected on the grounds of the provincial courthouse in Vancouver, British Columbia. The pole is a British Columbia fir, 205 feet in length, weighing approximately 5 tons after being dressed and allowed to season six or eight months. It will be set in a foundation of concrete 10 feet deep, giving it a height of 195 feet above the ground.

Electrification of Swiss Railways

A CONSULAR report states that Swiss federal engineers are watching with much interest the experiment of operating the Lötschberg Line by electricity, and that if it succeeds the St. Gothard will undoubtedly be equipped with the same motive power. In fact, the electrification of all Swiss railways seems to be the logical outcome of the fact that Switzerland produces no coal, but on the other hand is rich in water-power resources.

Steam Road Pavers

THE accompanying illustration shows a steam engine road paver at work on a long stretch of concrete extending out of Milwaukee.

Similar machines have been operating at Cleveland, Ohio, with a paving process consisting of a liquid asphalt combined with other ingredients which is mixed with sand and stone cold, and laid in this form.

This machine has a capacity of 20 cubic feet of loose material unmixed or 15 cubic feet of mixed concrete. The loading skip is 8 feet wide, permitting three wheelers to empty their barrows at once. The power plant is centrally located, the boiler being underslung. The loading skip has a very wide nose, so that it discharges into the mixing drum quickly and without any clogging tendency. The distributing spout is 15 feet long and is equipped with blades. As this distributor revolves it will of course continue mixing the batch right up to the point when it is discharged in the street. The equipment will handle three batches at the same time. While one batch is being loaded into the skip, another batch is being mixed in the drum and the third batch is being discharged from the distributor.

All levers are banked in one place, so that the engineer has absolute control of the machine, and can operate it himself. This machine is equipped with steering wheel, forward and reverse traction mechanism, compensating gears similar to those used in an automobile. As a two-bag machine the capacity has been greatly increased, the records made this season showing that it will easily average from 180 to 200 cubic yards of 6-inch base per hour.

It is said that the best record of a road paver of this type was 1,142 square yards of 5-inch base in less than 5 hours, at a cost of 3.7 cents per yard, with 23 men. Several other machines have nearly equaled this record.

Steam road paver used by the Milwaukee highway commissioners.

The Heavens in February

Uncertain Orbit of Delavan's Comet—Counting the Nebulæ

By Henry Norris Russell, Ph.D.

DELAVAN'S COMET, whose discovery was mentioned last month, is still under observation in the evening sky. It is however of about the eleventh magnitude, and is therefore visible only in telescopes larger than the average amateur possesses. Its orbit is still very uncertain; in fact, the results obtained by different computers differ radically, indicating that this again is probably one of the cases where two solutions of the problem are theoretically possible. That is, there might be two quite different orbits, so situated that a pair of comets, moving each in one of them, might be in line with the earth at the dates of all three observations, though before or after this interval of time they would appear to separate slowly from one another in the sky.

In such a case it may not be till some little time after the discovery of a comet that it can be distinguished with certainty in which of the two possible orbits it is actually moving, though ultimately this can always be done.

In the present instance, the preliminary orbits, computed from observations on three consecutive days, are described by the computers as "very uncertain." Messrs. Einarsson and Nicholson, at the University of California, deduce a highly inclined orbit, with the very small perihelion distance of one twentieth of the earth's distance from the Sun, and perihelion passage on June 28th, 1914. Kobold, on the other hand, finds the inclination small, the perihelion distance one ninth greater than that of the Earth, and the time of perihelion passage as March 2nd.

If the latter orbit is nearly correct, the comet should remain in the evening sky, and move northward and eastward, gradually growing brighter until the end of February, but probably not reaching the naked-eye limit.

According to the ephemeris computed from this orbit, the comet should be in 3 hours 6 minutes right ascension, and 4½ degrees north declination on January 28th, the last date for which the calculations are made. Extending the ephemeris roughly, we find that on February 13th it should be in about 8 hours 35 minutes, plus 14 degrees, moving northeastward at an increasing rate.

If the alternative orbit is correct, the comet will increase enormously in brightness, and be a very conspicuous object next June; but until further and better computations are available, it is of no use to attempt to say more. We may console ourselves with the knowledge that, according to either orbit, the comet will continue to grow brighter until well into March, so that the fuller information which will no doubt be available next month will not come too late.

Of other astronomical publications which have recently come to hand, perhaps the most interesting is a paper by Prof. Fath, formerly on the staff of the Mount Wilson Observatory, upon the number of nebulæ shown upon photographs with the great 60-inch reflector. The plates upon which these nebulæ appear were taken in accordance with Prof. Kapteyn's "Plan of Selected Areas," in which certain regions of the sky uniformly distributed over the heavens and about 15 degrees apart, are photographed with long exposures, so that studies may be made of the positions, motions, brightness, color, etc., of the very faint stars (which are so numerous that it is hopeless to try so much as to count them over the whole area of the heavens). Upon the plates of 139 such regions (distributed from the North Pole to 15 degrees south declination) Prof. Fath has identified 167 previously known nebulæ and 864 new ones, most of which, of course, are small and faint. If these selected areas are typical of the whole sky, as there seems good reason to suppose, the whole number of nebulæ in the heavens, capable of being distinctly photographed with the 60-inch reflector, giving one hour's exposure on the fastest plates (Lumière Sigma), should be 162,000. Many of the larger of these nebulæ show distinctly the familiar spiral structure. The smaller ones are usually too small to show any such details; but on account of their usually elliptical form, Dr. Fath considers that a large proportion of them are also unsolved spirals.

The distribution of these nebulæ over the heavens follows the law, long known to be true, that they are *least* numerous in the Milky Way, and thickest strewn near its poles. In fact, on the diagram which Prof. Fath gives, showing the whole number of nebulæ (including his discoveries) photographed in each region, the Milky Way is immediately conspicuous as a broad blank belt. Most of the plates in the Milky Way show no nebulæ at all, some exhibit one or two; while the four regions nearest to the north galactic pole contain no less than 227 of them—nearly one quarter of the number found in the 139 regions photographed at Mount Wilson.

One of Prof. Fath's results shows that the number of nebulæ in the sky is not as great as had previously been supposed. The best previous estimate, based upon 104 plates taken at the Lick Observatory, had put the whole number of nebulæ in the sky at half a million—three times larger than the present figures. Though the exposures of the Lick plates were three hours long, Dr. Fath shows that the greater sensitiveness of present day plates, and certain other advantages of the Mount Wilson reflector, make it possible to photograph equally faint objects with the exposure of one hour which he used. Dr. Fath however clears up the difficulty by recalling that the Lick photographs were made primarily for the study of certain conspicuous nebulæ. The great number of faint nebulæ shown, in addition to the bright ones, on the resulting plates led to the estimate that there must be half a million in the whole sky. But these brighter nebulæ, like the fainter ones, are strongly clustered in some parts of the heavens, and hence the Lick photographs are mainly of regions which are much richer in nebulæ than the average of the sky. The Mount Wilson plates, being taken on a plan which was carefully designed to avoid giving an undue preference to any region of the sky above any other, are free from this tendency, and hence the number of nebulæ, estimated from them, is probably nearly correct.

NIGHT SKY: FEBRUARY AND MARCH

The Heavens.

As our map shows, the finest region of the sky is now in the southwest and west. The twin stars of Gemini burn near the zenith, attended by their fainter companions. Below them in the west shine the ruddy Aldebaran, the golden Saturn, and the brilliant and fiery Mars. Capella, with its lesser neighbors in Auriga, is high in the northwest, with Perseus and Andromeda below.

The incomparable Orion brightens the southwestern sky, followed by the noble outline of the Great Dog, whose minor stars seem fainter than they really are, since the surpassing brilliance of Sirius quite outshines them. Compared with these constellations, those of the eastern sky are dull. Leo, high up and almost due east, is the most prominent group. Below it is the greater part of Virgo, and to the right rises the huge length of Hydra, stretching from near the zenith to the horizon and below it.

Arcturus has just risen, a little north of east. Farther north and higher up is the Great Bear, now splendidly displayed. The Little Bear is on the right of the Pole, and Draco, Cepheus and Cassiopeia are low on the northern horizon.

The Planets.

Mercury is an evening star all through February, and is very well placed for observation. To be sure, he is almost at his nearest to the Sun, being in perihelion on the 21st, and at his greatest elongation, 18 degrees 8 minutes east of the Sun, on the following day, but this very nearness makes him exceptionally bright, while his favorable declination, about 8 degrees north of the Sun, keeps him in sight until 7·10 P. M., an hour and a half after sunset.

At this time he is in Pisces, not far from the vernal equinox, but remote from any bright star. Since he appears brighter than Saturn, and equal to Mars, there can be no possible difficulty in identifying him.

Venus is in superior conjunction with the Sun on the 11th. Theoretically, she is a morning star before this date, and an evening star afterward. Practically, she is invisible throughout the month.

Mars has passed opposition, and is receding from us and growing fainter; his apparent stellar magnitude changing from —0.6 to +0.01 during the month, corresponding to a loss of half his brightness.

He is nearly stationary in the western part of Gemini, moving westward at first, then retracing his path eastward, but a little more to the south. In the telescope, he shows a disk varying in diameter from 14 seconds on the 1st to 10.8 seconds on the 28th, and distinctly gibbous, like the Moon two days from the full. Jupiter is a morning star in Capricornus, and rises about 6 A. M. on the 15th, so that he is too near the Sun to be easily seen.

Saturn is in Taurus, conspicuously placed, setting a little after midnight on the 1st, and about 10 30 P M on the 28th.

Uranus is morning star in Capricornus, but is too near the Sun to be seen.

Neptune is in the western part of Gemini, his position being 7 hours 53 minutes 21 seconds + 20 degrees 27.0 minutes on the 2nd and 7 hours 50 minutes 58 seconds + 20 degrees 33.8 minutes on the 26th. He is of the eighth magnitude, and so can be seen even with a good field-glass, but he can only be distinguished from the faint stars all around him by the aid of his motion (making diagrams from night to night) unless a powerful telescope is available.

The Moon.

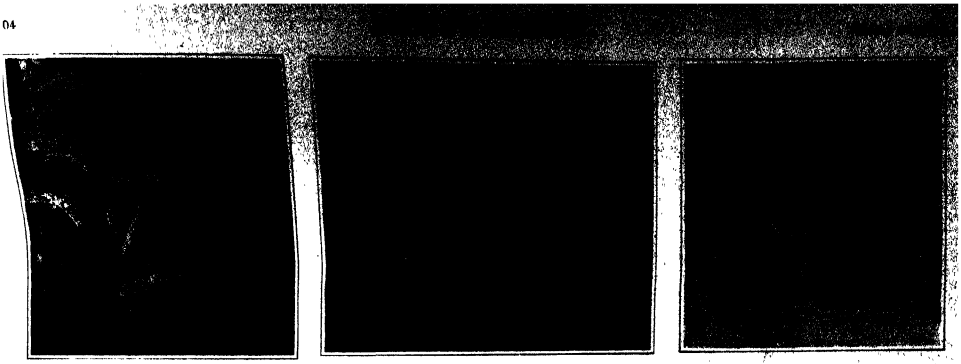
The Moon is in her first quarter at 6 A. M. on the 3rd, full at 1 P. M. on the 10th, in her last quarter at 4 A. M. on the 17th, and new at 7 P. M. on the 24th. She is nearest us on the 12th, and farthest away on the 28th.

She is in conjunction with Saturn on the 5th, Mars on the 7th, Neptune on the 8th, Jupiter and Uranus on the 22nd, Venus on the 25th, and Mercury on the 26th. In the case of Mars, an occultation is visible from certain parts of Asia, but not in our part of the world.

There is an annular eclipse of the Sun upon February 24th, but it is unlikely that it will be observed at all, unless from some ships at sea, for the region from which it may be seen lies entirely in the South Pacific and the Antarctic regions.

Princeton University Observatory.

To Stimulate Internal Combustion Turbine Development.—It is proposed that the Royal Automobile Club of Great Britain offer a suitable prize for the best practically useful rotary or turbine oil or spirit engine satisfactorily applied to a motor vehicle and entered for trial under R. A. C. regulations in 1915. It is believed that in so far as invention has progressed, sufficient inducement is offered for the expectation that inventive genius may solve this troublesome problem, and the prize will be offered as a stimulus. The amount of the prize has not been stated.



Three of the types of motor truck fenders that have been approved by the city of Detroit.

Fenders for Commercial Vehicles

THE question of the necessity for some sort of fender on commercial vehicles long has been pondered by municipal authorities in nearly every large city where the steadily increasing number of heavy self-propelled motor trucks serves always as more or less of a menace to life and limb and property. Not until now, however, has any concerted action seeking to a solution of the problem been taken. The city of Detroit, which is literally the hub of the American automobile universe, has taken the bull by the horns, so to speak, and has made it compulsory upon the owners and operators of commercial vehicles to equip them with fenders, as, a long time since, the traction companies were compelled to equip their rolling stock with them. The action of Detroit in thus compelling the use of such devices is taken as but a prelude to similar action on the part of Chicago police authorities and those of other large cities in the United States, and, incidentally, it opens up a large field for inventors of contrivances of the like. Three of the types of fenders that have been formally approved by the Detroit authorities are illustrated herewith, though the pictures scarcely can be taken as an indication of exactly what the police department wants, for it has given no inkling nor idea nor specifications of its particular desires It is stated only that the lower bar of the fender submitted for approval must be not more than six inches from the roadway when the truck is being operated either light or loaded on the city streets.

Motor Truck for Mine Rescue Work

THE recurrence of mine disasters, revealing as it does the almost pitiable equipment that is available for the relief of entombed miners, has served to emphasize the need of modern apparatus and appliances with which to carry on rescue work, and acting upon the suggestion conveyed by the successful use of commercial motor vehicles in other fields, the Bureau of Mines of the Department of the Interior at length has developed a plan which revolves chiefly around the use of a new and special type of vehicle thoroughly and properly equipped for the purpose.

The vehicle itself, which already has been delivered to the Bureau of Mines in Pittsburgh, is illustrated herewith and from the picture some idea of the completeness of its equipment may be gained. Instant access to everything the truck carries for rescue or hospital work is absolutely essential, of course, and for this reason the body, except for the space occupied by the crew, is virtually a series of lockers and compartments and the interesting feature of them is that in nearly every case they open from the outside and are held closed only by snatch hooks

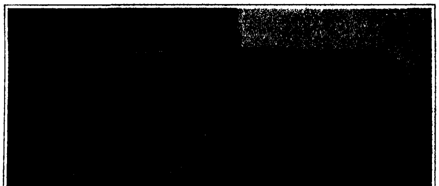
The equipment of the truck is most complete; the devices it carries form an uncommonly long list, including even the caged canary that has proved so useful in determining the existence of poisonous gases. By way of emphasizing the great amount of apparatus that is carried it is interesting to note that there are included no less than ten complete resuscitating outfits. The oxygen tanks, of which there are six, are carried beneath the body on a sub-frame and are so placed that they can be drawn forth from outside the truck. The oxygen pump is operated by the truck engine and is mounted at the left side of the chassis. Directly behind the driver's seat there is a series of compartments containing a tent, 22 feet of hose, three miner's picks, three shovels, a four-pound sledge hammer and two axes. The seats for the crew are behind these compartments and beneath them there is more storage space with another large locker, made up of a series of shallow drawers below the steps at the rear. These drawers serve to hold saws, hose couplings, reducers, spanners and 200 feet of half-inch rope.

In the central compartments along the body there is a life line reel, a complete telephone system for mine communication, and a various assortment of necessaries such as compasses, tools, and snatch blocks and tackle. Stretchers and fire extinguishers are disposed on the outside of the body by means of special hooks. On the running boards there are two more large boxes which are used to house mine lanterns and other miscellaneous equipment. Completing the equipment there is an eight-inch swivel headlamp mounted on the dash.

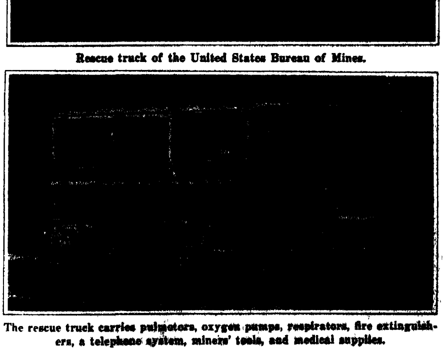
Motor Truck "Emergency Wagon"

EMULATING the practice of street railroads and gas and electric light companies that must of necessity be ready for all kinds of emergencies, a prominent commercial vehicle manufacturer has prepared and placed in service the emergency wagon that is shown by the accompanying illustration. The wagon is a light commercial vehicle chassis upon which there has been placed a special body equipped with tools, spare parts, and, in fact, everything that may be necessary to succor a crippled car on the road; the equipment is complete even to an extra pair of wheels which may be seen carried at the back of the body. In the picture, the emergency wagon is shown towing a disabled car which is a little the worse for an encounter with a trolley car. The front of the touring car rests on an extension on the emergency wagon, as may be seen, and when this extension is not in use it folds up out of the way.

Emergency truck towing a machine damaged in a trolley car collision.



Rescue truck of the United States Bureau of Mines.



The rescue truck carries pulmotors, oxygen pumps, respirators, fire extinguishers, a telephone system, miners' tools, and medical supplies.

Motor Truck Queries and Answers

P. A. S. writes: "I want to get a two-ton truck, but am puzzled as to the reasons for the two distinct types, i. e., those having the motor forward of the seat—as in the pleasure car—and those in which the motor is placed directly under the driver's seat and floor boards. Can you give me the advantages of each type?"

A. Much depends upon the purposes for which you intend to use the truck and the type and size of body you will find necessary. A motor placed forward of the driver's seat, under the conventional hood, is exceedingly accessible and nearly all parts can be reached easily from a standing position. This design serves to increase the wheelbase of trucks having bodies of only moderate size, and therefore adds to the stability, balance, and ease of riding. Beyond certain limits, however, a long wheelbase becomes a disadvantage. Some designers consider that the motor placed under the driver's seat renders the entire outfit more compact and enables a greater amount of space to be devoted to the body. Although such motors may seem to be somewhat inaccessible, they are in reality easily reached. The driver's seat is either made to tilt to one side or the other, may be removed entirely with but little exertion, or the floor boards and sides may be taken out so that any part of the motor will be exposed. However, the space occupied by the motor of a large truck is so small by comparison with the length of the body that it matters but little whether the motor be placed forward of the dash or under the seat. Leading truck manufacturers produce both styles, and we would not advise that this be a determining factor in the selection of a truck—unless you are to be cramped for room in your garage and need every inch in wheelbase length that you can save.

G. D. P. asks: "Why do we not see more kerosene used as a fuel for motor cars in this country? Do you believe its future lies in its use in the truck or pleasure car? I understand one make of pleasure car has been produced that is intended to use kerosene as a fuel."

A. The fuel problem has not assumed

Wireless Telegraphy and Telephony

Simply Explained

170 Pages, 156 Illustrations By ALFRED P. MORGAN **Price $1.00 Postpaid**

The simplest, latest and most comprehensive popular work published on wireless, for the wireless operator, amateur or professional!

This is undoubtedly one of the most comprehensive treatises on the subject, and a close study of its pages will enable one to master all the details of the wireless transmission of messages. The author has filled a long-felt want and has succeeded in furnishing a lucid, comprehensible explanation in simple language of the theory and practice of wireless telegraphy and telephony.

The book treats the subject from an entirely new standpoint. It is well illustrated by over one hundred and fifty interesting photographs and drawings. All diagrams have been made in perspective showing the instruments as they actually appear in practice. The drawings are carefully keyed and labeled. Many of the photographs are accompanied by phantom drawings which reveal the name and purpose of each part.

A book the wireless experimenter cannot afford to be without. It enables one to design and construct apparatus. Also valuable to the layman

Firestone
Truck Tires

Tire Equipment for motor trucks is a science in itself. Experienced truck operators no longer bargain on the basis only of such a size, such a mileage adjustment, at such a price.

The Firestone practice of closely classifying all delivery, hauling and transportation requirements has put tire equipment on a different basis—as much better as it is different.

Your class or classes of tire needs, for maximum truck efficiency at minimum cost, are among those analyzed by the Firestone experts.

There is a Firestone tire to meet each and every need, made to specifications, with uncompromising accuracy.

That is the tire which will cost you least to use—though it may cost most to build.

That is the tire which the Firestone man, whom you call in for consultation, will recommend for your requirements—and only that.

Firestone Salesmen sell Service. They sell most protection to truck mechanism, most miles without wheel trouble or delays, most miles per gallon of fuel

Most mileage—
Most service—
Per dollar

the serious aspects in this country that is the case abroad. It is in the countries in which we find gasoline at forty, fifty, and even sixty cents per gallon that the greatest interest in kerosene carbureter design is manifested. Notwithstanding the fact that one of the leading pleasure car manufacturers has produced a model, a part of the regular equipment of which is a kerosene carbureter, we believe that it is the truck owners who will first take up the use of kerosene on a large scale. The reason for this assumption is easily understood when it is remembered that a touring car can travel from eight to twenty-five miles on a gallon of gasoline, whereas the mileage of a truck on the same quantity will be from eight to ten. Furthermore, gasoline is a much cleaner fuel to use, inasmuch as any that may be spilled when the tank is filled will quickly evaporate without injury to the varnish, upholstery, or other surfaces of the car. Kerosene, on the other hand, is not as volatile, and any drops left on an exposed surface will soon collect dust and detract from the general "spick and span" appearance of the car. As comfort, utility, and pleasing appearance are most sought after in a touring car, and as economy is paramount in a truck, it is evident that gasoline, as it increases in price, will be in greater demand for the former than for the latter.

Winter Sports in Switzerland

(Concluded from page 92.)

The social form of tobogganing is bobsleighing, which is unquestionably the most enchanting kind of sleigh riding. The inventor of the "bob" is an American, Wilson Smith, and St. Moritz prides itself on having first introduced this sport in 1890. The bobsleigh is composed of two pairs of steel runners, one behind the other, on which rests a wooden seat, about ten feet long and about one foot from the ground, capable of accommodating from about four to six people.

The bobsleigh is now a machine which is the result of a thousand careful experiments, exactly tested and practically constructed. With it results are obtained of which the inventor at first certainly never dreamed. The putting together of the different parts, the dimensions, the weight, the materials of which these parts are made, the construction of the steering apparatus, the choice of brake, all this the sportsman has to study and carefully test, if he would take part in this modern exercise with the fullest success.

Through the simultaneous bending of the team at the curves, greater swiftness is attained, and in addition time is gained by certain motions, carried out at the command of the leader.

On a straight run, the guidance is comparatively simple, though care must be constantly taken, because slight imperceptible unevenness of the run turns the bob continually from its proper direction, and the steersman has to use the greatest attention. With constantly stretched guiding ropes, he must have the two front runners ever in feeling, and guide the bob softly like a well ridden horse. He must also, by steering with presence of mind, be able to parry at once a possible shake. Therefore, in a kind of way, he uses the qualities both of a good horseman and an efficient motorist.

On the curves, which almost form a semicircle, care is to be taken, in the first place, as to the correct entrance. If the entrance be good, the curve is already half done. If the bob runs with full speed to rise over a summit, then it is necessary to guide it with an iron fist through the curve. In coming out of the curve, the triumph of skill is shown in taking one in the opposite direction steadily and without upsetting.

The runners should be of medium length, and not too thick. Leaden ballast of between 50 and 100 kilogrammes (110 and 220 pounds) is always carried. The lead is fitted in plates under the seat board, more in the middle and behind than in front. The runners must be kept quite smooth, and the steering apparatus and brake be always well greased, in order to work easily and correctly. Another very enjoyable snow sport, in the Alps, is ski-

Do You Remember When This Event Occurred?

How Many Times Have You Ever Said "Hello"?

How many times a day do you suppose that little salutation is called over the telephone?

By the way, are you old enough to remember the sensation of amazement that greeted the *first* telephone?

That first wire stretched from Boston to Somerville and—Wonder of Wonders!—people were talking to each other over a distance of three miles.

That was nearly forty years ago.

So long ago it seems like ancient history, doesn't it? But just think! At the time that first telephone was causing so much excitement, Richmond Straight Cuts already had an established reputation as the *Perfecto* of Cigarettes.

Time erases many incidents from the memory—but quality is lasting. Quality makes an impression that years cannot wipe out. Time cannot diminish the popularity of Richmond Straight Cuts—they are still the best of all Virginia Cigarettes.

Impartial Economical Mechanical Supervision

The Servis Recorder gives you supervision at all times over your delivery and shipping equipment.

The **Servis Recorder** supervision is mechanical—therefore accurate, impartial and economical.

The **Servis Recorder** tells you when the vehicle began and stopped work—

The number of hours it was in actual service.

How much delay there was in loading—

How many stops were made.

How much time was taken for lunch—

How much overtime, if any, was made by the driver.

Lets you know any unauthorized use of the vehicle.

Permits you with certainty to lay off vehicles in dull season.

Raises the standard of efficiency of your employees—

The Servis Recorder is self-contained. It is not connected with the running gear or motor in any way.

The **Servis Recorder** works equally well on horse wagons, motor trucks or sleds.

It is the one dependable device that never fails.

What the **Servis Recorder** has done—what it will do for you—will be gladly told upon request. That it will save money for you is certain. To inquire how will not obligate you.

We invite correspondence.

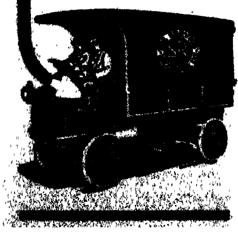
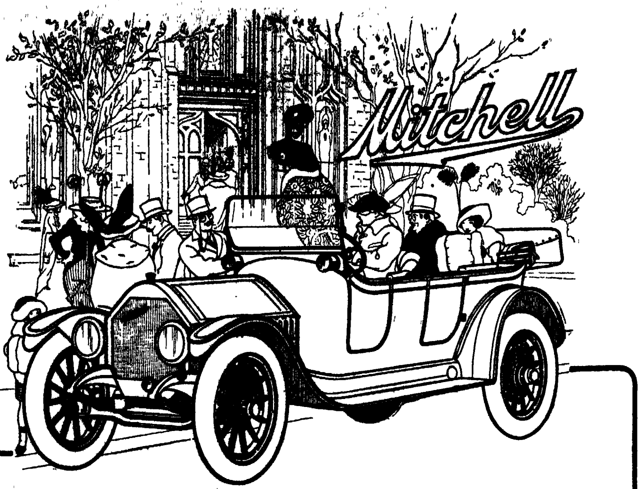
The **Servis Recorder** has been adopted by more than 35 Railroads for use on switching and transfer locomotives.





Eighty Years of Faithful Service to the American Public

The Mitchell-Lewis Motor Company has the enviable record of *eighty years of faithful service to the American public.* Bear this fact in mind when you get ready to buy a car, for it operates as *insurance of quality.*

No thoughtful business man ever buys a *commodity* or a *luxury* or a *necessity* without looking into the character of the men who make it. This rule of trade is more imperative in the purchase of an automobile than almost anything else you can name.

Eighty years of faithful service is an asset *of no uncertain value.* This company held the respect of the early settlers of the western country because of absolutely honest merchandise in the shape of farm wagons. It established its standing before automobiles were known. When it embarked in the automobile business, it clung to the policy that made its farm wagon business famous. And its automobiles are famous *for the same satisfying reason.*

You've got something behind you when you buy. Our standing and prestige constitute *a bulwark of safety.* Add to this the remarkably fine character of the Mitchell Models and your purchase is *as solid as the Rock of Gibraltar.* Ask any farmer in America what he thinks of the old Mitchell-Lewis Wagon Company. Ask any one of thirty thousand Mitchell automobile owners what he thinks of the Mitchell-Lewis *Motor* Company. Their reputation and reliability are precisely the same.

The Mitchell Models for 1914:

The Mitchell Little Six—fifty horse-power—132-inch wheel base—36x4½-inch tires—two- and five-passenger capacity - - -	**$1,895**
The Mitchell Big Six—sixty horse-power—144-inch wheel base—37x5-inch tires—seven-passenger capacity - - - - - - -	**$2,350**
The Mitchell Four—forty horse-power—120-inch wheel base—four cylinders—36x4½-inch tires—two- and five-passenger capacity	**$1,595**

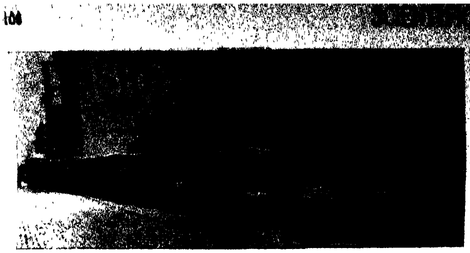
All Prices F. O. B. Racine, Wis.

Equipment of all the Mitchell Models Included in the List Prices Here Given:

Electric self-starter and generator—electric lights—electric horn—electric magnetic exploring lamp—speedometer—Tungsten Valves—mohair top and dust cover—Jiffy quick-action side curtains—quick-action rain vision wind-shield—demountable rim with one extra—double extra tire carriers—Bair bow holders—license plate bracket—pump, jack and complete set of tools.

Mitchell-Lewis Motor Co.
Racine, Wis, U.S.A.

Eighty years of faithful service to the American public.



A Motor Truck is primarily and essentially a Truck Motor. For the engine bears the brunt of the work. It must conquer the 30% grade; must forge along under overload; must be able to run hour after hour at maximum governed speed; must withstand the misuse of green drivers. Against the negligence of hired drivers, as well as against the competition in trade, the owner must guard himself. He does—with a Continental motor.

Continental Motors

To generate the power required to meet the rigorous demands of commercial service a truck motor must be able to get every ounce of energy from the fuel. As every driver knows, only the finest type of engine can do this successfully. Lubrication, cooling, alignment, must be perfect; machining must be perfect—plus. *In every one of these essentials Continental Motors excel.*

Ten years of manufacturing experience, an engineering corps intact since the organization of the company; the co-operation of the big technical experts of America and Europe, and extraordinary facilities for economical production, have made this motor pre-eminent—and America's Standard.

Why, then, are Continental-equipped trucks in their class, lower in price than those of competitive makes? Because Continental motors, used by over one-half of all the firms manufacturing motor trucks in this country, and built in factories having 45,000 capacity, can be produced at a lower unit cost, and because the expense of selling a Continental-equipped truck is lower. This motor cuts down "selling overhead." It has a business reputation. Its credit of good-will has never been impaired by a failure to deliver. And 80,000 indorsers of its credit are today using Continentals in cars that are pleasure cars in fact as well as in name, and in commercial cars which bring their owners steady profits.

Business Demands the Best. Continental Motors Meet That Demand.

ing. Its home is in Norway. As a [illegible] and indispensable means of [illegible] it has been used there for centuries. In past times it has been taken up, in a [illegible] fashion, by many countries. As a sport, however, ski running, even in Norway, is still in its youth. The peasants in Telemark, a Norwegian valley, were the first to make the ski a sporting implement. We must thank them that skiing quickly made its way. The performances of the Norwegian ski runners cause universal admiration. Everywhere the ski quickly found a hearty reception, and, to the present day, the number of its votaries increases unceasingly.

There are various shapes of the ski, short and broad, long and narrow, and all with their special purpose, but no form is so well suited for use in mountains, forests and lowlands as that of the Telemark valley.

The length of the ski should depend on the height of the runner; he should just be able to reach their points, when standing upright with outstretched arms, the ski being placed perpendicularly on the ground. Only ash or hickory is used, other kinds are hardly worth consideration. Ash, especially the mountain ash, gives a superior material. Hickory is harder and wears better but is heavier.

"Binding" is the name for the arrangement used for fastening the ski to the foot. Every year new methods are brought out, and patented, but the fundamental system is hard to improve upon.

As further requisites for the ski runner should be mentioned the single and double stick, the fur lining to prevent back slipping, and when on a tour, extra straps and ski points, carrying straps and repairing materials, ought to be provided.

It may interest some to read of gigantic jumps on skis. The longest known jump, to the present time, was executed by T. Smith with a distance of over 49 yards, from the Bolgen jumping platform at Davos, but unfortunately he fell, so that this performance could not be counted, and the record for acknowledged jumps is held by his brother H. Smith with 48 yards. Those astonishing performances attract large crowds of on-lookers.

Foolproofing the Motor Truck

(*Concluded from page 97.*)

which formerly received but scant lubrication, are now provided with grease cups which require only a quarter of a turn each day to supply the necessary lubrication to these parts.

In considering the points covered in the foregoing article, it must be remembered that such designs and attachments as mentioned will not be necessary on all trucks, for many commercial vehicles are designed especially to serve the purposes of those firms who intend to employ only expert chauffeurs. Even such drivers, however, are not perfect, and the tendency of modern truck design is to eliminate all cause of worry on the part of the owner. But, paradoxical as it may seem, in eliminating a part of the "personal element," it is a psychological fact that, in one instance, at least, it has been catered to. The growing application of electric starters to motor trucks is based, not so much on the desire to save work for the driver, but rather on the wish to overcome the one feature of gasoline truck operation in which the electric vehicle was formerly far superior. No matter how expert a driver may be, he will be almost certain to leave the motor running during short stops, and if these are frequent, the gasoline consumed by the motor when the truck is idle may exceed the amount of fuel used during the actual progress of the vehicle. Furthermore, if a gasoline truck is used under these conditions on routes on which the stops are close together and of varying duration, the wear and tear on the motor will be at least appreciable at the end of the year. It is the attachment of the starter, therefore, that is expected to overcome this objection to the use of a gasoline truck for short hauls and frequent stops, for it is hoped that its appeal to the driver's mechanical instincts will prompt him to use the device in preference to leaving the motor running.

"There's the Car for Economy"

NO one knows this better than the expert mechanic at your garage. He's been expecting this sweeping change in automobile construction. He knew that the demand for economy has been growing and growing until the public could wait no longer.

Now the heavy car is doomed. It costs too much to run. The light car, the high grade car, the car of comfort, quality and speed, will take its place. The Jeffery is here.

The Jeffery Four is the first high grade, light weight, quality car of comfort produced in this country to sell at $1550. The same type of car has been sold before at $2500 and more. The man who before had to buy the big, bulky car is coming down for economy and the man who before had to buy the cheap car to gain economy is coming to the Jeffery standard for comfort.

Three things made the Jeffery Four possible at this price—capital, equipment and experience. Few manufacturers in the United States could produce a car of this quality at this price. Two of these would not do it because they are entrenched in the low priced field. Some could not do it for at least eighteen months. All others could hardly hope to accomplish it, lacking capital, equipment and experience.

The dealers were quick to recognize these facts. The public is rapidly coming to a realization of their importance. Good mechanics knew that it must be so, but they did not expect this ultimate type of car to come so soon.

Electric starting and lighting, without chains, gears, bearings or belts Left hand drive and center control

Imported annular ball bearings throughout, (Speed up to forty miles an hour, shut off your engine and coast half a mile) Spicer universal joints, combination force feed and splash oiling system Leather ring coupling between clutch and transmission

Four forward speed transmission—the lightest and easiest to operate

High grade, full floating type rear axle, on imported annular ball bearings—a delight to the motor wise. Vanadium steel springs and axles

Bosch duplex ignition, Rayfield carburetor, pressure feed gasoline tank with gauges on tank and dash, demountable rims, advanced type of body designed by Rothschild

Jeffery Four equipment includes Neverleek top; top cover; rain vision windshield; electric lighted dash with Stewart-Warner speedometer, ammeter, air and oil pressure gauges, four position light switch and small storage compartments; Klaxet horn, foot rest; extra demountable rim with carrier, and complete tool and tire equipment. Engine driven power tire pump, $25 extra

WANTED!

Interesting Photographs of Inventions and short, bright articles on scientific, industrial and mechanical topics

The Editor of the **Scientific American** would like to receive them.

The articles should be so simply worded and so free from technical expressions that an intelligent business man will readily understand them.

The photographs should, whenever possible, present a human being handling the device illustrated.

More professional and business men read the Scientific American than any other periodical—men who are employers of labor and users of machinery, and who want to know about new inventions and discoveries that may help them in their business. But they want their scientific news briefly and simply.

Accepted articles and photographs will be paid for promptly.

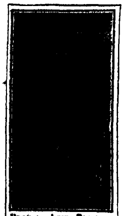
The POSTAL Saves You Money and Safeguards Your Health

THOUGHTFUL people throughout the country arrange policies in the POSTAL LIFE INSURANCE COMPANY because, *first*, it supplies sound legal-reserve protection at low net cost and, *second*, because it performs an important service in *health-conservation* for its policyholders.

The Company dispenses with agents; it deals *directly* with the public, and policyholders save, and may deduct from their *first* premium (monthly, quarterly, semiannual or annual), *a guaranteed commission dividend* corresponding to what *other* companies pay out the *first* year to their *agents*, less the moderate advertising charge.



POSTAL LIFE BUILDING
35 Nassau Street, New York

This Dividend ranges up to 40% of the Premium on Whole-Life Policies

In *subsequent* years, POSTAL LIFE policyholders can deduct the *agent's renewal-commission* of 7½% as paid; also an *office-expense saving* of 2% making up the

Annual Dividend of 9½% Guaranteed in the Policy

The Company also apportions and pays the *usual contingent dividends* that other companies pay.

Furthermore the Company's Health Bureau performs an important service in *health conservation* by issuing Health Bulletins for the benefit of its policyholders and by granting to those who desire, one medical examination each year at the expense of the Company, thus detecting incipient disease in time to check or cure it.

By doing business through the mails—*directly*—it not only effects important savings for policyholders, but also brings the benefits of insurance-protection and health-conservation to the *remotest sections of the country*, thus performing a public service akin to rural free delivery and the parcel post.

For the reasons here stated and others, the POSTAL LIFE is justly designated "The Company of Conservation"—of *money* and of *health*.

STRONG POSTAL POINTS

First: *Standard policy-reserves, now nearly $10,000,000. Insurance in force nearly $50,000,000.*

Second: *Old-line legal reserve insurance—not fraternal or assessment.*

Third: *Standard policy-provisions, approved by the State Insurance Department.*

Fourth: Operates under strict State requirements and subject to the United States postal authorities.

Fifth: *High medical standards in the selection of risks.*

Sixth: *Policyholders' Health Bureau arranges one free medical examination each year if desired.*

Write at once and find out the exact sum the Company will save you at your age on any standard form of contract—Whole-Life, Limited-Payment Life, Endowment, Joint-Life, or on a Monthly-Income Policy.

No agent will be sent to visit you: the POSTAL LIFE does not employ agents. Call at the office or write for full official information. Simply say:

Mail me insurance-particulars as per advertisement in SCIENTIFIC AMERICAN for Feb. 7

In your letter be sure to give:
1. Your full name. 2. Your Occupation.
3. The exact date of your birth.

POSTAL LIFE INSURANCE COMPANY
WM. R. MALONE, President

Fire Insurance Efficiency Engineers

As a manufacturer you have made your machinery efficient, but have you maximum fire insurance to protect adequately your efficient machinery?
We furnish indemnity, but as well a service of efficiency engineering on

Fire Protection
Construction
Hazards
Contracts
Rates
Maintenance

We will tell you about this service without charge. Write us

HARTFORD
FIRE INSURANCE CO.
HARTFORD, CONN.

ROTARY PUMPS AND ENGINES
Their Origin and Development

An important series of papers giving a historical resume of the rotary pump and engine from 1588 and illustrated with clear drawings showing the construction of various forms of pumps and engines. 38 illustrations. Contained in Supplements 1109, 1110, 1111. Price 10 cents each. For sale by Munn & Co. Inc., and all newsdealers.

What are You Doing to Get Repeat Orders?

There's only one reason why a wise automobilist purchases the same make of car TWICE. And that is, because he figures that this particular make of car gives longer, better service than ANY OTHER car of the same class. YOU know that a car's life and usefulness depend on bearings, as on few other things.

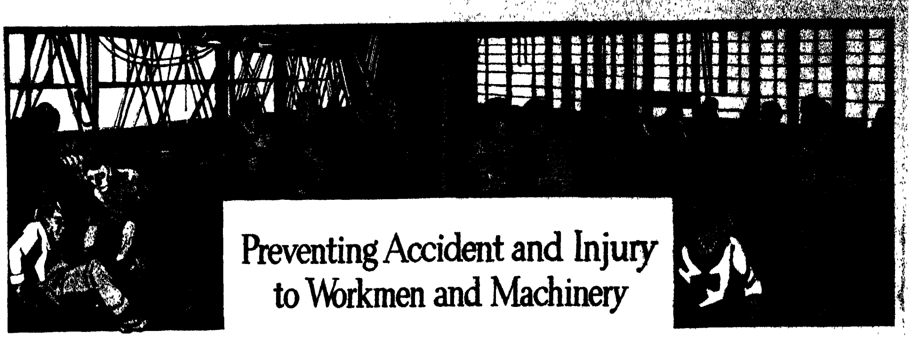
HIGH SPEED
NON-GRAN
BEARING BRONZE

The Only Non-Granular or Fibrous Bearing Bronze

Wears Twice as Long as Any Other Bronze Made

That's a fact about which there is no dispute, and it's a fact you can easily settle for yourself (as many leading car manufacturers have already done) by writing for special information as to how NON-GRAN will fit YOUR particular needs, preferably sending blue prints.

AMERICAN BRONZE COMPANY
[illegible] CARTON BLVD.
BERWYN, PENNSYLVANIA



Preventing Accident and Injury to Workmen and Machinery

"AN ACCIDENT!" The news flashes through the plant. There is a scurrying of many feet, then a lull.

"Anybody hurt?" is likely to be the first inquiry. Maybe the answer is, "Bretley broke his arm." Or may be the answer is, "Just a scratch, but the big cutting machine is a wreck."

It is a familiar story repeated with thousands upon thousands of variations month after month. The Manufacturers' Association says that 500,000 *avoidable* accidents occur within a year.

"Avoidable." Men are turning to that word—they have begun to consider safety with more care than ever before. New York established a Museum of Safety. A Congress of Safety has gone deep into this vital problem of applied conservation.

Safety is being made a science—"Safety First," a watchword.

And the science of safety finds its chief safeguard in *mechanical security.* To attain mechanical security in all the many avenues of its application no step is more direct than that made possible by Electricity.

For example, electric motors placed within the base or frame of a machine so as to drive the machine with gears or belts that are totally enclosed, make it practically impossible for man or woman to have clothing caught and life endangered.

Power application in this form cuts out all the many dangers of overhead shafting—the danger of falling sections, belt wheels, broken belts, which have filled the history of American manufacturers with so many tragic chapters.

Beyond this, it directly decreases fire danger by eliminating bearings that may be overheated to the point where they cause fire, as well as other frictions that are a constant fire danger.

The method of control is another "safety first" feature of the electrically operated shop. Motors are started and stopped by push buttons, located at the most convenient point on each machine. Whenever an overload or other unnatural condition of operation occurs, the motor stops automatically—*before* the condition becomes dangerous. This method of controlling power eliminates to a large extent the "personal element" as a factor in safety.

To decrease fire danger is to reduce insurance rates. In a still larger sense the increased safety of electrical power and motor drive are themselves an insurance that means unquestionable economy. It was declared at a session of the Manufacturers' Association that "a conservative estimate of the economic loss in this country, through industrial accidents, places it at a quarter of a billion dollars each year." The actual experience of manufacturers who have installed the modern system of using power made possible by electricity, proves that an immense reduction in the number and seriousness of accidents and injuries, and a vast saving of money penalties, may be confidently counted on to follow the extension of this system.

Add to this insurance the productive advantages of the motor drive method, in small plants as well as in large plants, the low cost of installation and of maintenance, the labor economies, the advertising effect of a clean, lighter, more attractive-looking plant, and the business wisdom of this method needs no further argument. Take up the matter today with your electric power and light company or any General Electric Company dealer or agent in your vicinity. You will find them more than glad to cooperate with you, and no matter how complex your problem may be, they have at their command the service of any part of our organization that may be most helpful to them and to you.

Electric lighting and starting equipment for motorcycles.

Electrically Lighted and Started Motorcycle

WHEN, about a year ago, one prominent manufacturer of motorcycles placed on the market a machine equipped with an engine starter of the spring type, thus marking a new era in motor bicycle construction, it looked as though the last word had been said. Now, however, there has been placed on the market by another maker a motorcycle which not only has a complete electric lighting system even to the dynamo, but which has an electric engine starter as well. This year in the motorcycle field, electric lighting is common, though so far only one maker has attempted to follow in the footsteps of the automobile engineer to the extent of equipping with an engine starter, too His machine is shown by the accompanying illustrations.

Compactness in the electrical equipment is absolutely necessary, of course, and this has brought about the development of a clever combined generator and starting motor that has a number of individual and highly interesting features. The combined unit is mounted just ahead of the engine, to which it is attached by means of bolts and straps. It drives and is driven through a roller chain which gives a reduction of approximately 2 to 1. The battery has six cells and is split into two units, half being on either side of the frame at the back of the seat post. For operating the head lamp and the tail lamp the voltage is six, but when used for starting purposes the cells are connected in series, giving 12 volts. To start the engine it is merely necessary to close a small switch on the handle bar. Immediately after the engine has picked up its own cycle of operations the switch is thrown the other way, making the necessary connections to charge the battery at six volts. The change in the mechanical unit from starting motor to generator is made automatically as the armature speed is increased. The machine is compound wound and with the batteries in a fully charged condition delivers about 420 watts at [illegible] amperes for starting, the motor being sufficiently [illegible] to [illegible] the gasoline engine at nearly 800 revolutions a minute. The time necessary to start the gasoline engine varies from about four seconds in warm weather to about 12 seconds in cold weather, provided the engine is in good condition.

The construction of the generator-motor unit is novel. The commutator is within the armature coils instead of being at the end of the armature shaft as is usual; thus great compactness is obtained. The four pole shoes are carried on the field piece casting and the brushes are mounted in holders on the case cover.

Obviously, some device to maintain the output of the generator practically constant regardless of vehicle speed is essential and this is contained in a casing mounted just above the generator-motor unit. This device performs a dual service, for in addition to preventing the charging current from mounting too high at high engine speeds it breaks the connection automatically between the generator and the battery when the voltage of the former becomes less than that of the latter, as when the engine is stopped, for instance

The battery, as already has been made plain, is contained in two cases carried at the back of the seat post The casings are substantial and the vents are so arranged that the electrolyte cannot be spilled in the event of the machine's being turned on its side. The generator-motor unit is quite small, measuring but 10 inches in diameter and 3½ inches in width.

Graphical Studies of Marriages of the Deaf

THE Volta Bureau possesses a card catalogue relating to 4,471 marriages of deaf-mutes, reported in Dr. E. A. Fay's work entitled "Marriages of the Deaf in America," published by the Volta Bureau. Each card is illustrated by a graphical diagram prepared by Dr. Alexander Graham Bell, exhibiting at a glance the number of brothers and sisters and children of the partners in marriage, and whether they were deaf or not. An analysis of these 4,471 marriages appeared in *The Volta Review*. No information concerning offspring was obtained in regard to 974 of the marriages; and in [illegible] cases the marriages took place within a year of the date of report, so that offspring had not then appeared. Eliminating the above, the table deals with 3,078 marriages of a year's standing or longer; 434, or 14.1 per cent, were childless, so that the children recorded were the product of 2,644 marriages Omitting two of these on account of incomplete returns, the table shows that 2,342 of the fertile marriages resulted in hearing offspring alone, and that in 300 cases deaf offspring were also produced.

Dr. Bell has now presented to the Volta Bureau a graphical study of the 300 marriages which resulted in deaf offspring, showing the ancestry of the husbands and wives, the number of children produced, and how many were deaf and how many could hear. The brothers and sisters of the ancestors are also given, showing how many were deaf and how many could hear, and each chart collates the information scattered through Dr Fay's book relating to deaf relatives in collateral lines of descent The marriages are designated by the same numbers used by Dr Fay in his published work. Additional details, preserved in the confidential archives of the Volta Bureau, are accessible to *bona fide* investigators upon request.

A New Building Material

THE French inventors of a new system of metallic wall covering claim quite a superiority over plaster or wood, and cheapness as well. On the laths are mounted light stamped sheet steel plates of handsome decorative design, made in a variety of standard sizes from 2 feet square up to 6 feet by 2 feet and the like. Ornamental cornices are also used, so that there is no difficulty in giving a metallic covering to ceiling and walls, and the effect is most handsome. The advantages of metal are numerous, for humidity does not penetrate, and good hygiene is secured from absence of microbes and insects. The thickness is not over 0.0012 inch and the weight 4 pounds per square yard. Matched joining of plates gives a uniform surface whose joints the eye cannot detect. Such joints are treated in place so as to be quite tight.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Is Our Target Practice Equal to the Best?

THE SCIENTIFIC AMERICAN recently stated that our target practice was probably no better than that of the other leading naval powers, and not nearly so good as that of one particular navy. We have frequently been asked which particular navy it is that is doing better work at target practice than our own. There is no reason for concealing the fact that it is the British navy which is so greatly in the lead, and that the cause of its superiority, as compared with our own, is its adoption of what is known as the "director system" of firing. Director firing was developed by Admiral Sir Percy Scott, and it was he also who elaborated the system of fire control by spotting, which he gave to an American officer, a close friend of his, when they were on the China station years ago—a system which has been steadily followed and equally improved in both navies for years; which is still in force in our navy; and which was abandoned last year in the British navy in favor of the vastly superior "director system" as devised by Scott.

In the old Scott system, which we are still following, there is a pointer at each gun, who tries to keep his sights continually on the target. When all the guns are loaded the fire-control officer sounds a "buzzer" at each gun, and on hearing this each pointer is expected to instantly fire his gun—*if he is exactly on the target.* If he is above or below the target he must not fire, but must wait for the next round. Now it is human nature to want to be "in the game," and too often the pointer will "let fly," whether he is on or off the mark. If his horizontal wire is above the target by ever so little his shell may drop a thousand yards over the target, if below he may be as much short. The result is that the spotter is bewildered by the wide range of "dispersion" as it is called and does not know whether the range for the whole battery should be put "up" or "down" or left where it is.

Now in the director system the errors due to the human element are eliminated by using one telescope and one pointer for the whole battery. Only one gun—the master or director gun—has a telescope and at this is placed the crack pointer of the whole ship's company. The other guns are trued up in parallel with the master gun and move exactly with it. The master gunner keeps steadily "on" the target, and the instant the battery is loaded he presses the firing button, and the guns being elevated to exactly the same degree, the shots fall bunched in practically the same place, and the spotter on the top of the mast is able to tell with great accuracy how far the splash is "short" or "over."

It is this cutting out of the errors of the individual pointers and consequent bunching of the shots that makes director firing such a great step in advance of the old Scott system, which we are still using. The spotter can quickly pull the salvos onto the target and hold them there unerringly.

Now for results. After spending no small amount of his own money in the purchase of gear with which to test his system on his own ship, Admiral Scott succeeded in getting it applied to a dreadnought, the "Thunderer." This ship was sent out with a sister ship, the "Orion," fitted for individual pointing, as practised by us to-day, and, under exactly identical conditions of wind, weather, range, and speed, she put four times as many shots through the target—at least so said the cabled dispatches at the time. So startling was the improvement that the British government voted the full sum necessary at once to apply the system to the whole fleet.

But there is nothing like first-hand information; and *we have it from Sir Percy Scott himself*, who during a lengthy conversation last year on director firing in general, informed the Editor that *the introduction of director firing had increased the hits in target practice for the whole navy over one hundred per cent.*

What then are we to make of the statement of Rear Admiral Joseph Strauss, U. S. N., Chief of the Bureau of Ordnance, before the House Naval Affairs Committee, on January 19th, that the Scott director system "had been experimented with in the American Navy and found not as accurate or satisfactory as the American method of firing salvos"? The American method is the old Scott method, and we have the best grounds in the world for stating that the director experiments referred to were not the true Scott methods, but only a guess at them, and a very wide guess at that.

This depreciation of director firing by Mr. Strauss is most unfortunate, made as it was to the House Naval Committee, on whom the further policy of advancement so greatly depends. For the information of the House we repeat that the Scott system has never yet been tried out in our navy; the SCIENTIFIC AMERICAN learned last year by personal investigation that director firing is absorbing the closest attention of navy artillerists throughout Europe; that because of the lack of initiative in this matter in our Bureau of Ordnance we are already far behind one great naval power in target results; and that in view of the active work being done in director firing by Germany (to mention one other power), the results of which, the writer is reliably informed, are very promising, we are in danger in falling behind that country in target practice as far as we have in battleship strength.

The "Safety First" Movement

WHATEVER may have been the sins of the great American trusts, a blind and cruel disregard of the physical welfare of their employees was not one of them. To be sure, there have been instances of long hours and arduous labor; but the men who had imagination enough to create corporations capitalized at half a billion dollars and more had also imagination enough to see the business folly of endangering life or of working a man to the point of exhaustion. Taken as a whole, accident prevention and welfare work have been more developed by our great industrial companies than by smaller manufacturers. Indeed, were it not for the salutary laws that have been passed in most States to check the frightful loss of life and limb that has hitherto marked the course of our industrial expansion, it is probable that those merciful provisions which stand not only for humanity, but also for good business, would still be confined to the trusts.

The history of the safety first movement in America is in that respect a duplicate of the history of the movement abroad. Long before the social democrats insisted upon the passing of those stringent accident prevention laws, for which Germany is famous the world over, the larger German manufacturing companies had instituted accident prevention and welfare systems that testified to their humanitarian instincts and their good business sense. Systematic accident prevention is at least fifty years old in Germany; in the United States hardly fifteen years old. While we can hardly boast that we have approached the high standard set by Germany, still the record which we have to show for our fifteen years is creditable indeed.

But much more remains to be done—how much can be gleaned by examining statistics. From a chart which was exhibited by the Prudential Insurance Company of America at the recent International Exposition of Safety and Sanitation, it would follow that there are 25,000 fatal industrial accidents per annum in the United States, and some 300,000 injuries. The more possibility of being able to state in statistics the approximate number of our industrial casualties is a step in advance; for as late as 1908 it was impossible to estimate with any accuracy at all what was the toll we paid in crushed limbs and snuffed-out lives. Now at least we know how vast is the problem to be solved, how much needless suffering we inflict and how much we lose in dollars and cents, because we have hitherto failed to realize the necessity of guarding men as well as machines.

It has been estimated that it costs about $300 to train a skilled workman to perform a new task, and that ultimately he represents an investment of about $2,000 to his employer. Considering the subject of accident prevention from this cold-blooded standpoint, our business policy has not been all too wise.

Now that there is an awakening of employers to the duty which they must exercise, now that employers' liability statutes have done away with the antiquated common law conception of negligence, we may watch for a very marked improvement in deaths and injuries.

As an example of the splendid work which the large corporations are doing in the education of their employees we may instance the Pennsylvania and New York Central Railways and the United States Steel Corporation. Elsewhere in this issue will be found pictures which tellingly set forth what the railroads are doing to make one of the most hazardous of occupations reasonably safe, and how the greatest steel manufacturing company in the world protects the thousands intrusted to its care. The work of the steel company is particularly difficult because it is dealing with employees who come from half a dozen different countries and who speak not one word of English. Railroad companies have their problems, too, because they are dealing with the most ponderous and at the same time the most swiftly moving machinery that we know.

It would be hard to estimate with any degree of accuracy how much money is annually spent in driving home the safety first principle; but it must run well up near a million dollars, if we take into consideration what the larger companies spend in issuing educational pamphlets, in employing lecturers, in installing safety guards in machine shops, and in maintaining splendidly equipped emergency hospitals. That it pays to do this is evident from the figures published by the Pennsylvania Railroad. Surely, the reduction of serious accidents to the shop employees of that company alone from five to seventy per cent is magnificent.

America's Need for an Aeronautical Motor Competition

IF we may credit the reports of progress in aeroplane design, the most serious requirement of aviation to-day is a suitable engine. Inherent stability has been provided in Dunne's invention; automatic stability in Wright's invention; nearly the limit of efficiency has been attained in propeller, wing and body design. When well above the earth, a skilled pilot, in whatever attitude, normal, oblique, or reverse, now feels sufficiently safe. Give the circus aviator a strong, reliable motor; he will perform anywhere, however forbidding the terrain beneath. To strength and reliability add economy, and the commercial aviator will make the aeroplane pay dividends by performing useful service to the community. What aviation most needs, then, is a strong, reliable, economical engine.

America has many motor firms, but too little exchange of ideas. An engine tournament, a public show of merits is needed. A competitive test of all the best aeronautical motors, followed by a published report, would be most serviceable to builders and users alike. An adequate testing plant, established by the United States Signal Corps, is now available at the Bureau of Standards, in Washington. All, therefore, that is required to launch a first-class competition is a monetary prize, or the guarantee of orders on a showing of merit, sufficient to attract the engine builders.

The SCIENTIFIC AMERICAN would recommend that a fund be established for a motor competition similar to that recently held in Berlin. The German Emperor offered, from his private purse, a prize of 50,000 marks for the best German aero motor. This sum was, by contributions from the country at large, soon swelled to 125,000 marks, and resulted in a competitive test of two or three score of the best aeronautical engines. Who will emulate the German Kaiser in America?

In our issue of August 31st, 1912, we commended the movement to establish a national aerotechnical institute. Such an establishment, under direction of the Smithsonian Institution, is now practically realized. It has the co-operation of four departments of the Government, including the Army and Navy, and of various private laboratories and air craft companies. It, therefore, needs only the approbation of Congress to make it truly national. The Aeronautical Advisory Committee of the Smithsonian Institution is especially qualified to receive and properly administer a prize for an aeronautical motor competition, more particularly since its membership comprises delegates from both the Signal Corps and the Bureau of Standards. We would recommend that the proposed prize and competition be placed in charge of this committee.

The Haze of 1912.—The remarkable turbidity of the atmosphere in the summer and autumn of 1912, with its attendant optical phenomena, has generally been attributed, as previously noted in these columns, to the presence of dust from the eruption of Mount Katmai, Alaska. However, the question as to the cause of this haze has recently been reopened by Dr. Barkow, who, as a member of Filchner's Antarctic expedition, observed similar phenomena in latitude 70 deg. south, as early as the middle of June, 1912, and during some months thereafter. Cirrus clouds of unusual altitude were noted, and the illumination of the northern sky at midday (with the sun below the horizon) was so bright that reading was possible for several hours. In other words, the phenomena strongly indicated the presence of some light-reflecting substance at an abnormal height in the atmosphere. As it is not thought possible that dust from Katmai could have traveled to the Antarctic so soon after the eruption, Dr. Barkow suggests that the dust was of cosmical origin, though its effects were probably heightened in the northern hemisphere by volcanic dust.

Science

Radium in Central Asia.—Large deposits of radium are have been discovered in the Ferghana district of Russian Turkestan.

Dr. E. A. Fath, director of Smith Observatory, Beloit College, has resigned his position as director of that Observatory in order to take up work as president of Redfield College, Redfield, S. D. He assumes his new office on March 1.

Captain Scott's Journals, kept by him during his antarctic expedition, have been deposited by Lady Scott in the British Museum, where they have been on view since January 17th, the second anniversary of Scott's arrival at the south pole. They comprise the three small, pencil-written books that were found on the explorer's body by the searching party in November, 1912.

A Swedish Antarctic Expedition, now in process of organization, is to sail in the autumn of 1915 and spend five years in exploring in the neighborhood of Graham Land, the coast of which was explored by a previous Swedish expedition, under Nordenskjöld, in 1902-03. The scientific staff will comprise ten men experienced in polar research. Arrangements are being made to have the expedition provisioned every season by whaling vessels, which have recently become very numerous in that quarter of the globe. The outfit is to include wireless telegraphy.

Steam Otter Trawlers had a phenomenally successful season on the Newfoundland Banks during the past year. This method of fishing has now assumed such importance as to cause anxiety concerning the conservation of the world-renowned Newfoundland fisheries. While the new methods involve less danger and hardship to the fishermen than the old, and are more certain and profitable, it is claimed in some quarters that by destroying spawn and small fish of no commercial value and uprooting the marine vegetation of the bottom, trawling will result in the rapid extermination of the fish and the ruin of the fisheries. In order to discourage this practice, the Canadian Parliament has passed a bill (the Hazen bill) to prevent French otter trawlers from coaling at Canadian ports.

The Newfoundland Reindeer Herds, established five years ago by Dr. Grenfell, have proved as great a success in Newfoundland and Labrador as have the herds of the United States Bureau of Education in Alaska, where the pioneer experiments were made. The original herd of 300 Lapland reindeer has now increased to over 1,200. In northern Newfoundland and in Labrador there are few horses or dogs for haulage purposes, while the Labrador dogs are vicious brutes which attack and devour even human beings. Harnessed to a sled, two reindeer will pull 500 to 700 pounds 30 miles a day, and they are also successful as pack-animals, carrying loads up to 200 pounds. The other economic uses of the reindeer are well known. After another season it is proposed to distribute the animals to the mission stations in Labrador, where eventually the Alaskan practice of lending small herds to the natives will probably be adopted.

The Condensation of Moisture in the Atmosphere—i. e., the initial step in the formation of clouds, fog, rain, hail and snow—has been explained for more than a generation by the presence in the air of myriads of minute (mostly ultra-microscopic) "dust" particles, each of which was supposed to serve as a center of condensation. The well-known instrument invented by Aitken, in 1888, in which, after a small measured volume of air has been cooled by expansion, the resulting droplets of water are inspected through a microscope and counted, is known as the "dust-counter," because it has been assumed that the number of drops formed in this process represents the number of particles of "dust" in the given volume of air. This idea is intrenched in the very latest works on meteorology in the English language, though qualified by the admission that in a highly supersaturated atmosphere, such as may be produced at will in laboratory but hardly occurs in nature, condensation also occurs on ions, in the absence of "dust." However, if we turn to recent German meteorological literature (e. g., Wegener's "Thermodynamik der Atmosphäre" or the third edition of Hann's "Lehrbuch der Meteorologie," now appearing in parts) we find that a new idea, after slowly taking shape in the scientific journals for several years, has now definitely crystallized into the belief that "dust," in any ordinary sense of the term, has comparatively little to do with condensation in the atmosphere. Yet it is still believed that the water-droplet forms around a something-or-other that is not water. Ignorance as to what this something is finds expression in its non-committal name of "nucleus" (German Kern). Perhaps it may be a molecule of a hygroscopic gas. Several such gases occur in small and variable amounts in the atmosphere. The whole subject is still in a highly problematic stage, the only definite fact being that "dust" has been shorn of its time-honored function as a cloud-maker, and that Aitken's Staubzähler has become a Kernzähler.

Aeronautics

A New Military Aeroplane.—On January 16th last, the aviator Espanel tried out at Villacoublay a new armored military biplane, constructed in accordance with plans furnished by the French Ministry of War. The apparatus is intended to repel dirigibles. It is armed with a rapid-fire machine gun.

Charles K. Hamilton.—An amazing career was that of Charles K. Hamilton, the aviator, who recently died in New York city. He was in the air before there were flying machines, for he it was who with cat-like agility saved himself from injury in more than one fall in experimenting with Israel Ludlow's gigantic kites. When the aeroplane appeared, Hamilton was in his element. His swoops and his dips thrilled thousands of spectators when flying was still a novelty. Perhaps his most notable exploit was his flight from New York to Philadelphia and return on June 13th, 1910—one of the most important cross country flights of its day.

Aerial Stowaways.—The enormous biplane built by Sikorsky was referred to in this column some weeks ago. A correspondent of the London *Telegraph* who resides near the military aviation ground at St. Petersburg, where the machine was berthed—no shed was large enough to contain it, so it had perforce to be kept in the open—and had frequent opportunities of observing the huge machine, both in the air and on the ground, supplies his paper with the interesting information that when the great biplane was well up in the air on one of its first trial trips, two workmen were discovered in the cabin who had stowed themselves away for the purpose of stealing a trip in it.

The Wright Stabilizer.—At a recent demonstration of the Wright stabilizer before the committee which awarded the Collier trophy to the invention, something more was revealed of the side control. It seems that in the actual device a gradual effect is assured, because a windmill takes the place of the servomotor which we described in our recent article on the stabilizer, and because a clutch is substituted for the three-way valve. An auxiliary propeller is rotated by the relative wind and thus furnishes an amount of power for working the side control, strictly in proportion to the disturbing force. A clutch, moreover, is obviously capable of a graded effect. Vanes might be provided to make the windmill face side gusts squarely. The idea of deriving proportionate power from the air itself in combination with pendulum control is certainly most ingenious.

Navy Flying Machine.—That aeroplanes should eventually be placed aboard all battleships was one opinion out of a number of important conclusions recently arrived at by a board of officers appointed for the purpose of drawing up a comprehensive plan for the organization of a naval aeronautic service. The board ordered by the Secretary of the Navy was composed of the following officers of the Navy: Captain W. I. Chambers, senior member, and Commanders O. B. Britain and S. S. Robison, Lieutenants M. H. Simons and John H. Towers, Naval Constructor H. C. Richardson and First Lieutenant A. A. Cunningham of the Marine Corps. The board emphasized the opinion that aeroplanes should eventually be placed on board all battleships. Also, that any group of ships on scouting duty or detached service, will require their services. The bulk of the stores, supplies and implements for these aeroplanes should be carried by the fleet auxiliaries so as not to encumber the fighting units. Special ships for aeroplanes and air craft generally should be considered, though not immediately recommended.

Prizes for 1914.—The most important prize to be won in 1914 is that of $25,000 which is open to British-built aeroplanes and engines over a 1,540-mile circuit of the British Islands, with an additional prize to the engine constructor. Then there will be a first prize of $25,000 for the best performance in a reliability trial, of a British-built engine, with an additional $200,000 in orders. Other big prizes which may be won in 1914 are $50,000 for the first aviator to fly from Europe to America; $100,000, with several minor rewards, for an aeroplane offering the greatest degree of safety, this competition being started by the Union Aerienne de France, and open to constructors of all nationalities; $2,000, offered by the Paris Municipal Council, for a race from capital to capital, probably to some place in the Near East, via Vienna and Budapest; $5,000 for a hydro-aeroplane race of 150 nautical miles, open to all nationalities, organized in connection with the Coupe Jacques Schnieder; $4,000 for an all-around France competition with sixteen stopping places; $4,000 for the circuit of Paris competition, the distance being about 125 miles; $2,500, offered by a newspaper, for a flight across Africa from Cairo to the Cape, the distance being about 5,600 miles; a prize to be given to the first pilot reaching Johannesburg; $2,000, offered by the Aero Club de France, for the longest direct non-stop flight; $1,800 Michelin prize for the greatest number of hits on a given target in competition for bomb throwing from aeroplanes.

Automobile

Lubrication of Worm Drives.—Advocating the use of either castor, sperm or lard oil for the lubrication of worm drives, Mr. Lanchester, inventor of the type of worm and wheel that bears his name, suggests that one is about as good as the other provided it is pure and free from acid. He suggests, too, that a mixture of any two of them may be better than one alone, for when they are mixed better control of viscosity is obtained. Thus, for instance, lard oil which has a tendency to solidify at temperatures lower than normal can be made more suitable and this objection removed by the judicious addition of sperm or castor oil

Spring Suspension of Cycle-cars.—Because of their light weight and narrow tread, the spring suspension of cycle-cars manifestly is a matter of the gravest importance. In this connection, it is interesting to note that of late several engineers prominent in the automobile industry have offered as their opinion that the cantilever type of spring seems best adapted for these light little vehicles. This type of spring possesses two cardinal advantages: It is less expensive to manufacture than many other types and in action eliminates practically all of the uncomfortable and often dangerous rebound that is a feature of nearly all other springs.

Danger in Over-powering Light Cars.—With the marked stimulus that has been given the building of light cars during the past few months there becomes apparent a danger that would seem to have been overlooked by a majority of manufacturers It is, briefly, that it is quite possible to over-power these little vehicles. As light vehicles they scarcely are calculated to withstand the abuse that must follow as the result of the possibility of high speed, which always exists as an invitation to the owner to exceed the moderate rate of speed conducive to longevity. With the powers that are being used in those cars that have put in an appearance, it is to be feared that odium will fall on the class almost before it has become established. Perhaps some sort of an engine-governing device would solve the problem.

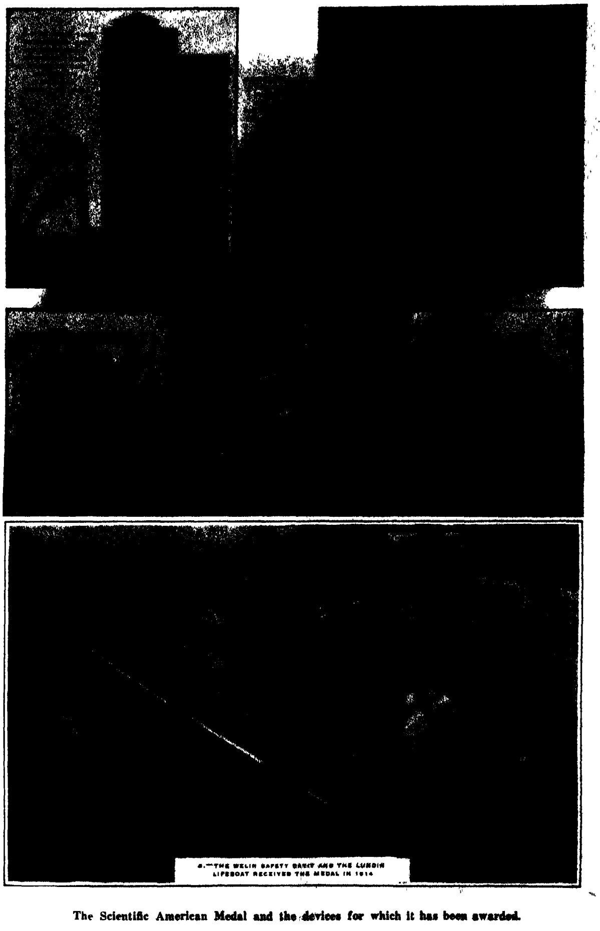
Noteworthy Performance of Knight Type Engine.—As a matter of record, the performance of a Knight type sliding sleeve valve engine recently under test at the hands of the Automobile Club of America is of considerable interest inasmuch as a new world's record for continuous operation was established The motor actually ran a total of 336 hours with the throttle wide open and the dynamometer load adjusted to hold the revolutions to 1,117 a minute The average horse-power developed, the bore and stroke being 4 and 6 inches respectively, was 38 3; maximum horse-power developed on a subsequent test was 53 6 at 1,682 revolutions per minute. The gasoline consumption during the test was 1,744 gallons, though this figure, unfortunately, is inaccurate for the reason that an undiscovered leak in the fuel line increased the consumption The average consumption during the time when, presumably, there was no leak was 31.5 pounds an hour, and during the last 10 hours this dropped off to 30 8 pounds. The gasoline tested 61.6 Baumé at 60 deg. Fahr. All told, 131 6 gallons of lubricating oil were used. At the conclusion of the run, the motor was found to be mechanically perfect and unusually free from carbon deposit, the sleeves and ports were free from burns and the piston rings were free. Throughout the run no trouble of any kind was experienced, except that the fan belt broke, and after being replaced once, finally was discarded after it again failed.

The Electrically-operated Brake Appears.—There has just been placed on the market—it was exhibited at the recent automobile show in Grand Central Palace—a novel and interesting mechanism for electrically operating the emergency brake on automobiles. Briefly, the apparatus consists of a tiny electric motor operating at extremely high speed and driving through worm gearing a drum over which a cable attached to the brake actuating mechanism is wound. The motor draws current at six volts from the battery used for the electric engine starter. The control is placed on the steering column and is one of the most interesting parts of the whole assembly. When the lever is moved so as to close the circuit and open it again immediately, the electric motor is set in motion, but the movement of the drum is limited by the action of an automatic circuit breaker which cuts off the current when the drum has made a predetermined part of a revolution. As the drive is through worm gearing, the brake cannot release itself and remains lightly applied. Subsequent movement of the control lever in the same manner repeats the process, applying the brake still more tightly and a further repetition of the initial function permits further revolution of the drum, applying the brake with the maximum pressure. A friction clutch between the motor and the drum protects the cable from breaking. The brake may be released progressively, as it is applied, or at once. Similarly, moving the control lever the limit of its travel applies the brakes to the maximum pressure almost instantly. The apparatus may be applied to any car, new or old.

The Scientific American "Safety First" Medal

The Five Winning Devices

By William H Tolman Ph D Director of the American Museum of Safety



6.—THE WELIN SAFETY DAVIT AND THE LUNDIN LIFEBOAT RECEIVED THE MEDAL IN 1914

The Scientific American Medal and the devices for which it has been awarded.

AS early as 1867 Dolfus, a French industrialist, aroused by the increasing number of accidents to labor in factories and workshops, due to the fact that there was little or no attention paid to the safeguarding of dangerous machinery, organized an association for the prevention of accidents, and founded what was the beginning of a museum of safety devices. To-day some of these original models may be seen in an honored section of the Paris Museum of Safety Devices. In 1890 a museum of safety devices was opened in Vienna; in 1893 a second in Amsterdam, followed by similar organizations in Munich, Berlin, Moscow, Zurich, Paris, and Milan, until now there are twenty-five museums of safety.

One of the most encouraging signs of the moral uplifting of the race is the unmistakable growth in these later days of the humanitarian sentiment. The dignity of the human body, the sanctity of human life, are swiftly emerging to their full and proper recognition. The reproach has lain too long at our doors that, as a people, we were so madly bent on the pursuit of wealth that we cared little who might fall by the way, if only the goal were swiftly and grandly won To the question "How much then is the life of a man worth more than a sheep?" we have made answer by rolling up a record of over half a million annual maimings and killings that may well put us to the blush Therefore it is gratifying to realize that the movement set on foot by the American Museum of Safety for the promotion of an American museum of safety devices is meeting with marked success

After seven years of vicissitudes the Museum has emerged as a great institution for promoting safety. The work of the Museum has often been commented upon in the SCIENTIFIC AMERICAN

To further stimulate the prevention of accidents and the promotion of industrial hygiene, five gold medals are placed at the disposal of the American Museum of Safety for annual award. Three of these are in general fields. One, the E. H. Harriman Memorial Medal, founded by Mrs. E H. Harriman, will be competed for by American steam railways, for the best record in accident prevention and hygiene, affecting the public and its own personnel, during the current year A fifth medal, known as the Rathenau Gold Medal of the Allgemeine Elektricitäts-Gesellschaft of Berlin, is to be awarded for the best device or process in the electrical industries, safeguarding industrial life and health, made through an American institution The last award in the series will be the Anthony N Brady memorial medals.

The oldest medal is that given annually by the SCIENTIFIC AMERICAN, and, therefore, it is fitting that in a special number devoted to "Safety First" we should review the five awards which have been made of it

In 1908 the award was given to a device for safeguarding life at sea. Fire on shipboard is as much a crowning horror as a collision, and any means of detecting it and putting it out should be added as equipment to all vessels. The award was made to the Rich Marine Fire Indicating and Extinguishing System.

A brief description of the device will prove of interest A pipe runs to each hold, storeroom, bunker, etc., where it terminates with a flat cap or smoke collector. The pipes from the various holds and bunkers are assembled from fore and aft and are carried to the bridge or to the wheel house. Here they are arranged in banks in a case, which is practically air-tight. Each pipe has a removable smoke spreader bearing a number. Directly over the pipes is an electric fan which can be actuated continuously or at intervals. In front is a clock provided with means for making contact with an electric bell every fifteen minutes. It is the duty of the officer of the watch to set the motor in motion if it is not running continuously, and to look through the glass front at the pipes. Very little suction is necessary to draw the smoke from any incipient fire, and it is readily detected with the aid of the electric light which is inside the case. If no fire is found the officer "rings in" on a time clock like a watchman's detector, showing that he has made the proper inspection.

In 1909 there was no award, but in 1910 the SCIENTIFIC AMERICAN Medal was given to the Patent Scaffolding Company of New York for the design and construction of masons' suspended platforms. The following is a brief description:

The construction will readily be understood by reference to the engraving. The scaffold is interrupted so as to make sections ten feet long. At the ends of each section of planking are a pair of winches secured to a horizontal iron beam serving to support the planks. The winches are composed of a drum around which wire rope is roved, and the necessary supporting members. The upper end of the wire rope is secured to an outrigger by an anchor bolt, thus serving to support the scaffold. To the drums are secured ratchet wheels. A lever serves to actuate a pawl, which raises or lowers the scaffold by means of the ratchets which serve to turn the drum which winds up the cables. As the sections are small, one man can raise his section very quickly by a few strokes of the four levers at each corner.

1911 passed without any exhibit being made which was worthy of the medal, but in 1912 it was awarded to the Norton Company for their well-developed and carefully thought out accident prevention devices applied to grinding wheels. The company has at all times made an effort to fool-proof in every possible way all apparatus of its manufacture by means of safety hoods, flanges, etc. In addition to the specially referred to safety devices, accidents from other sources have been guarded against, by means of proper housings of all gears or other pieces of mechanism, also stops which prevent the mounting of a larger wheel than the given machine has been designed for; dust suction systems for the protection of both operator and machine; leather spark brushes, so attached to the hood as to protect an operator's clothing from sparks; adjustable rests, etc. In 1912 the SCIENTIFIC AMERICAN Medal was awarded for the fourth time. This year it went to the Draeger Oxygen Equipment Company for their "Pulmotor," which possesses such human interest for the many lives it has saved in cases of gas poisoning and electric shock as well as drowning.

The cylinder contains 11½ cubic feet of pure oxygen. The oxygen passes from the reducing valve to an injector which has the property of drawing in a large volume of air with a certain force of suction, and propelling that air forward with equal force through the flexible tube in front of the injector. This suction and delivery injector, therefore, serves as a motor, alternately filling the lungs by pressure and emptying them

(Concluded on page 130.)

The Business Side of the "Safety First" Principle

How Accident Prevention Pays

By David S. Beyer, Manager Accident Prevention Department, Massachusetts Employees' Insurance Association

ANYONE who visited the recent exposition of Safety and Sanitation at the Grand Central Palace in New York, must have been impressed, especially if he were previously unfamiliar with the scope of the safety movement in the United States.

Even those who were best acquainted with what is being done all over the country for the prevention of accidents, could not restrain their expressions of surprise that so much safety material from so many varied sources could be gathered in a single exhibition hall. It reminded one of an annual automobile show, in the variety of equipment represented and the enthusiasm with which the proprietors of the various booths displayed their exhibits to visitors.

To be sure, some of them had an eye to business; the man who broke dollar goggles for all comers just to show how strong they were, undoubtedly expected to recoup his losses through future orders. This, however, could not be the controlling motive that induced Germany and Holland to send their contributions from across the seas, nor did it influence the United States Steel Corporation, the New York Edison Company, the Westinghouse Electric Company, the Pennsylvania, Chicago and Northwestern and Baltimore and Ohio Railroad Companies and scores of others who do not manufacture safety devices for sale.

Anyone who came away without realizing that the safety movement is on in earnest in this country must have kept his eyes shut and his ears closed.

Ten years after Spain passed her first workmen's compensation act, we began to adopt similar acts in an effort to correct the long standing wrong.

Germany made the start thirty years, and England fifteen years ago.

But when we move, we move quickly. With the safety movement scarcely six years old in this country, we can point to hundreds of plants which are equal, if not *superior*, to the best in Europe as regards the safety of their employees. And the list is constantly growing.

During that time we have proven several things: in the first place, that *accident prevention pays*. By this is meant not only that it pays from the humanitarian standpoint, but that it is a good investment looked at in terms of cold cash.

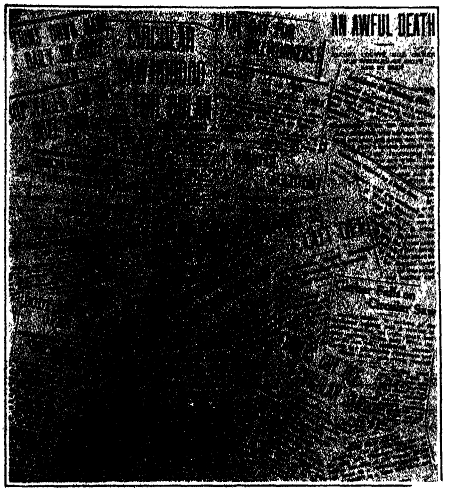
The Economy of Accident Prevention.

This is not the only object that appeals to a business man, but it is a very important one; he must run his business economically, or it will become impossible for him to continue in business. It can now be demonstrated that one of the most effective economies he can introduce into his plant is scientific accident prevention.

Take for example the appended chart of the United States Steel Corporation, giving the results of six years of safety work; this shows a reduction of forty-three per cent in the accidents to employees during that period; stated in terms of human units, this means that nearly nine thousand men were saved from death or serious injury.

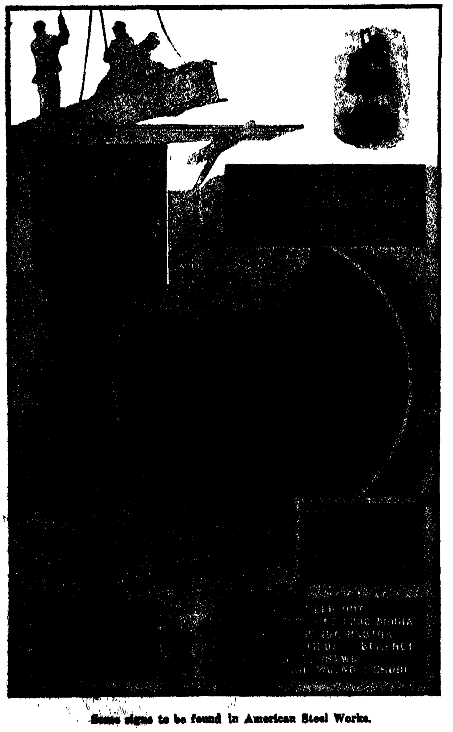
With the compensation of injured workmen costing a million and a half dollars a year, it takes little further calculation to show that the million dollars per year which the corporation has invested in safety devices is paying several times as much as if it had invested the same amount in Government bonds.

And that is *only* the *direct* saving, to which several incidental items can be added. An accident to a trained worker generally means that a "green" hand must be employed to fill his place. It costs money to break in a green man, and in doing so further loss is generally involved, through the reduction of output and the spoiling of more or less good material. Furthermore, this man, being unfamiliar with the hazards in his new work, is likely to injure himself or some of his fellow employees before he is fully trained. Still another possibility of loss confronts the employer. The new man may after all prove unsatisfactory for the work, and have to be replaced by a third man, thus doubling the training expense.



AN AWFUL DEATH

Newspaper reports that would not have been published if the "Safety First" principle had been observed.



Some signs to be found in American Steel Works.

It is impossible to estimate these items of cost accurately, but no one can deny that they exist in definite form and that this expense can be saved by avoiding injuries to trained employees.

The Chicago and Northwestern Railway Company has not been working at accident prevention so long as the United States Steel Corporation, but, nevertheless, shows a reduction in accidents for the last three years of 20.9 per cent in the number of persons killed and 23.7 per cent in those injured as compared with the last year previous to the organization of safety committees.

The fact that such committees have been organized in sixty-eight railroad companies, including such systems as the Buffalo, Rochester and Pittsburgh, Chicago, Burlington and Quincy, Chicago Great Western, New York Central, Pennsylvania, Norfolk and Western, Southern, and Union Pacific, etc., indicates how thoroughly convinced the officials of these great organizations are that safety work pays.

The accident reductions which have been obtained by the Eastman Kodak Company may be mentioned as characteristic of another type of industry. As a result of two years safety campaign, decreases in accidents aggregating 44 per cent have been made, as shown by the table on the next page.

Many other cases might be cited, but these are sufficient to show the possibilities of this work

Workmen's Compensation Acts and Accident Prevention.

In considering the saving effected by cutting down accidents, it should be remembered that this item of expense has been growing larger year by year. During the last three years about half the States in the Union have passed workmen's compensation acts, the immediate effect of which has been to multiply by several times the cost of accident settlements.

It is probable that within a short time all States will have similar laws, so that the question becomes much more important financially than it has been in the past, on account of this increase in cost.

The principal way in which this loss can be cut down is by preventing the accidents. When it becomes generally recognized that 30 per cent to 50 per cent of all industrial accidents are preventable, some by mechanical safeguards and others by educating the men not to take chances, a great step will have been taken toward bringing about the desired end.

It must be admitted that as a rule it is the small plant that is the hazardous one, and it is the proprietor of the small plant who is the hardest to convince that safety work is needed. Generally he has heard of numerous accidents occurring in the big plant across the way, and is quite ready to concede that safety work is a prime necessity there, but he feels that conditions are different in his own plant. He has very few accidents, and when one does occur it is the fault of the injured man himself.

He does not stop to think that the reason why there are more accident in his neighbor's plant than in his own, is because it is so much larger, and that in reality he may be having more accidents in his small plant in proportion to the number of men employed. A small plant may go for months or even years without an accident, just as a department of the same size in a large plant may have the same experience; but where several thousand men are working in any industry, a number of accidents are sure to occur every week.

The mistaken idea comes in trying to form a general opinion from a limited field of observation. A wide experience and the knowledge of thousands of accidents are necessary before it is possible to recognize what accidents are common and may be expected to reoccur.

An Insurance Company's Experience.

By way of illustration, the experience of an insurance company covering about nine hundred plants may be cited. During the course of a year there were ninety-six accidents reported from persons falling down stairways. At the same rate of frequency, it would be ten years before this particular accident would occur in each of the nine hundred plants. It is altogether probable that before the end of ten years the first accident would be forgotten, or, even if it should be remembered, those most familiar with the accident conditions would be likely to say that since this kind of accident happened so seldom, it was not worth considering.

As a matter of fact, one hundred accidents from one cause, even in a thousand plants, shows that this is a serious source of hazard, and one which would warrant the expenditure of considerable sums for hand-rails, safety treads, additional lights, etc., by means of which many of the accidents could be prevented. When this is made clear, the safety provisions are usually forthcoming.

Another element which explains the reasons why many people may consider an accident rare and unusual when in reality it is common and of frequent occurrence, is the general tendency to hush up information of this sort as completely as possible.

An accident is an unpleasant thing at best, and everyone likes to forget about it as soon as possible. Thus it sometimes happens that men in the building next to the scene of an accident know nothing about it. The same accidents may be happening all around them, yet when one comes under their personal observation, they consider it a strange and unique "Act of God."

Not long ago an inspector was talking to one of the officials of an electric company about the protection of 500-volt electrical equipment. This official was in a position where he should have been familiar with all the details of the subject as far as his particular company was concerned, having been connected with it for a number of years; yet he remarked, "To my knowledge no one has ever been killed in this company from five hundred volts."

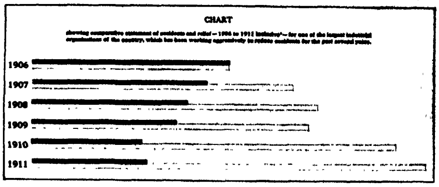
The inspector replied, "To *my* knowledge two men have been killed from this voltage in your own company during the past two years."

This official had not heard of the accidents because, as is common practice, they were kept quiet. When such ignorance of accident conditions exists within a single company, it is not strange that the people in one plant should not know about the accidents in others. Thus the proprietor of the small plant fails to have any conception of the great number of accidents that happen in the industries about him, and the part that he can play in reducing his small proportion of the whole.

It is an unfortunate thing that there must be accidents, but when they do occur, it is still more unfortunate if the one valuable result is lost: this result is the lesson which might be learned from one accident, to the end that other accidents of a similar nature might be prevented.

One of the things that is very much needed is greater publicity as to the accidents which occur, and the manner in which they occur. The records published by the various States, with two or three notable exceptions, are so vague and indefinite as to be of no value whatever from this standpoint; one of the important aims of correlating the various safety movements in different parts of the country, should be the accumulation of accurate statistics, classified along uniform lines, and giving sufficient detail to convey a definite impression as to the exact causes of the vast number of accidents occurring every year.

The pioneer work in accident prevention has been done. It has been demonstrated that accident prevention pays from the financial standpoint, as well as from the more important aspect of humanitarian considerations. The way in which accidents may be prevented has also been well marked out, and is constantly being more clearly defined. What is now needed is widespread publicity, so that every man in every industry in our country may know the advantage of this great movement, and do his part to carry it forward.



Heavy lines show reduction in serious and fatal accidents among employees of the United States Steel Corporation, using 1906 as a basis. Dotted line shows increase in total casualty expenses per employee, using 1906 as a basis. The increase is explained by the fact that the corporation in question has made more and more liberal payments to its injured men, until, in 1910, it adopted a voluntary compensation scheme, in which all men injured in the regular course of their employment are compensated, regardless of whether they were partially to blame for the accident or not. The slight increase of serious and fatal accidents in 1911 over 1910 is due to a change in classification of accidents established January 1st, 1911, resulting in more accidents being classed as "serious" than formerly were so classed. The fatal accidents in 1911 were 27.27 per cent less than in 1910. During 1910 and 1911, $3,183,000 was expended for compensation to injured workmen, and $1,750,000 for the installation of safety devices. *The number of serious and fatal accidents shows a decrease of 43 per cent since 1906,* thus indicating that the large expenditure for safety equipment was amply justified, and gave a good return on the investment.

COMPARATIVE STATEMENT OF ACCIDENTS PER 1,000 EMPLOYEES FOR THE YEARS 1910, 1911 AND 1912.

Nature of Accidents.	Rate per 1,000.		
	1910	1911	1912
Fingers and hands between punch presses and shears	14.38	9.28	4.30
Fingers and hands against woodworking saws	4.79	4.41	2.69
Fingers and hands into woodworking cutters	2.18	2.32	1.25
Bruises, burns, lacerations and injuries of minor importance	44.74	38.41	27.97
Falling off ladders, platforms and slipping	10.91	6.26	6.45
Injured around elevators	.80	1.39	.72
Injured around emery and other grinding wheels	3.46	1.16	1.61
Obstructions in passageways and doors	.53	.46	1.25
Falling tools, materials, etc	9.59	7.42	4.65
Fingers and hands under drilling and boring machines	8.53	1.86	3.41
Fingers and hands into automatic screw machines	1.07	.70	.90
Injured around lathes and milling machines	4.79	.46	.72
Stepping on nails	4.00	2.55	2.05
Injured on machines of special nature			2.15
Total accidents per 1,000 employees per year	109.72	71.68	61.13
Reduction of accidents per 1,000 employees since year 1910		38.04	48.59
Percentage of reduction		34.67	44.29

A Wireless Danger Aboard Ship

THAT wireless may at times prove dangerous aboard ship, has just been pointed out by the United States Bureau of Navigation, Department of Commerce, part of whose duty it is to see that the laws governing the use of wireless telegraphy are obeyed. The same wonderful means of communication which already has saved the lives of so many at sea, may result, if not properly guarded, says the bureau, in a danger and a menace rather than a safeguard to some vessels.

The bureau is preparing to call the attention of the entire shipping world to this danger, and through its inspectors to warn them. The danger is that electrical sparks may set fire to vessels carrying gasoline or other substances which generate an explosive gas.

In a communication which has just been sent out to radio inspectors by A. J. Tyrer, acting commissioner of the bureau, the following statement is made:

"When inspecting the radio apparatus on tank vessels or cargo vessels carrying gasoline or similar substances which generate an explosive gas or any other explosive which might be ignited by electric sparks caused by the operation of the radio apparatus, you will pay particular attention to the insulation of the antennæ, to metallic rigging or equipment of the vessel in which currents may be induced by the action of the radio apparatus, and to the wiring and electrical equipment of the vessel in which currents may be induced by radio apparatus so as to cause sparks to jump between wires or between small gaps.

"In general this matter should be brought to the attention of masters of vessels, steamship owners and wireless telegraph companies.

"If upon inspection sparks of the above character are found, the matter will be reported to the master of the vessel, the steamship company or its agents, and to the company operating the wireless apparatus, and the dangers pointed out."

The operation of radio apparatus on board vessels generates in the antennæ enormous potentials or very high voltages. If the insulation of the antennæ is in any way defective, this high potential causes sparks of electricity to pass over the insulator in an effort to reach ground. In some cases, even though the insulation is efficient, high potential surges are generated in metallic rigging, such as guys, etc., by electromagnetic induction. Small insulated spaces or air gaps are sometimes found in parts of a vessel's rigging in the vicinity of steel guys, etc., and the high potential surges induced in these conductors often jump across the gaps in the form of electrical sparks. It is a very common occurrence on board vessels when the wireless apparatus is operating to hear the crackling of small sparks, and or sometimes at night these small sparks can be seen. In many cases special precautions are taken to avoid this phenomenon, and the guys and rigging are split up into insulated sections in such a manner as to be out of resonance with the radio apparatus so that the surges cannot take place.

Many tank vessels and some of the cargo vessels carry gasoline or similar explosive material and are equipped with wireless apparatus. In some cases vent pipes from the storage tanks are led up the masts and have openings in the vicinity of the antennæ or some of the guys where electric sparks might occur due to the radio apparatus, and it is entirely within possibilities to assume that under certain conditions the sparks might cause an explosion. It is well known that gasoline vapor in explosive engines is ignited by means of electrical sparks which are identical in every particular with the sparks above described.

Oil and Wool from Pine Needles

PINE-NEEDLE oil is a product derived from the leaves of our pines. It has been extracted for a great many years and is well known the world over as a remedial agent against rheumatism and allied complaints. It is a volatile, colorless liquid obtained by distillation of fresh needles, young twigs, and one-year-old cones of our western and southern yellow pines. In order to produce oil of the best quality fresh green needles must be collected during the spring of the year, preferably in the beginning of June. Pine-needle pickers go from tree to tree and select the young, thrifty green leaves at the ends of twigs, which yield about 0.55 per cent of volatile oil. Those of old trees, which are dry and tough, produce much less and of much poorer quality.

A number of years ago this oil was supplied by a number of small stills or ordinary pharmaceutical distilleries. The still itself is a very simply constructed apparatus consisting of a closed copper kettle, into which the material is placed. Steam is admitted under pressure and passed through the contents from the bottom of the kettle. The volatile oil is vaporized by the dry steam and passed off with the saturated steam through a long coiled condensing tube. The condensed steam and oil are collected in a receiver, and the oil, which is on top, is drained off.

There has been an increasing demand for pine-needle oil and the small stills which could not compete with the larger concerns have now practically all ceased to operate. The large distilling plants with all the recently introduced secret devices are now able to produce all the oil required for home consumption and also for export. In this way the oil has not only been improved, but the cost of production has been considerably diminished. Some of the large stills have a capacity of from 30,000 to 60,000 gallons annually. The price of the purified oil varies from $20 to $30 a gallon. Cheaper oils are frequently adulterated with turpentine oil.

The mass left in the kettle after all the oil has been driven off may be regarded as a by-product, and it is sometimes due to the close utilization of this material that the business is made a profitable one. The needles are removed from the kettle and boiled in a soda solution until all the resinous matter and non-fibrous tissue are separated from the fibers. It is next passed through a series of washing, drying, and heating processes, which sometimes require 24 hours. After they are put into a machine to separate and loosen the fibers, they are bleached and put in assorted packages and sent to the different markets, where they are sold for pillow and mattress stuffing. The fiber will retain its odor permanently and is considered very healthful and vermin-proof. It was on account of these two qualities that the best hotels and hospitals of Europe used this fiber in their mattresses.

The material when properly prepared is sometimes known as pine wool which may be spun and woven into fabrics. It is very strong and is advantageously employed for many of the purposes for which hemp is used. In Europe this pine wool is made into jackets, drawers, and stockings of every description as well as flannel for shirts, coverlids and chest protectors. Knitting and darning yarn, quilts, wadding, deadening paper for walls and floors, and a great many other articles are manufactured from this wool.

Labor in South America—a Word of Warning

To the Editor of the SCIENTIFIC AMERICAN:

Now that the Panama Canal is nearing completion, a number of American workers will be ripe for a change of scene. They have been receiving good wages and will have money in their pockets. It is probable that the love of travel and change will lead some of them to South America; in this connection a word of warning is due.

I am writing from Colombia—the country nearest to Panama—a country which is, in popular belief, the El Dorado of miners; a country in which several railroads are in operation and in course of construction; and one which has recently come into notice in connection with oil and other concessions.

The American or European firms operating in Colombia usually engage white employees from home, under contract. There is therefore small chance for the man who casually drifts into camp. One difficulty is the extent of the country—more in difficulty of travel than in actual miles. A man on first landing at Barranquilla or Cartagena finds workmen who do not object either to hard work or long hours, earning from 40 to 60 cents a day. He learns that up country are mining camps staffed with white men, and probably decides to try his luck. The only road is on the river Magdalena, on steamboats traveling about six miles an hour. When the moon is full these boats travel (or may travel) full time; at other times they often tie up to the bank during the dark hours. The journey may therefore take four days or more than a week. On leaving the boat a spot is chosen where a feeder railway runs something less than a hundred miles into the country, and from there travel is over roads such as are unknown in the wildest of the northern Rockies. Local transportation is on mules, but this is expensive for a man who is not a native, probably with a slight acquaintance with the language and not conversant with the customs of the country. He will soon learn one custom which is prevalent though not universal, the habit of charging foreigners double what is charged to a native. The mining camps may be fifty or more miles apart, or several days measured by time of travel, over roads which are a succession of steep climbs or descents, in a country of perpetual summer heat, the only division of seasons being wet and dry. At the camp he finds the usual men under an agreement from home. If he is an artisan, a blacksmith or carpenter, he may get work at something slightly under a dollar a day. This is enough to live on, but not enough from which to save a stake with which to reach home. If he is unsuccessful he drifts to the next camp, there to repeat the experience.

The native Colombian is a very adaptable man, and he is clannish. Therefore we find the railroads manned by natives and little chance (as there is said to be in the Argentine) for American engineers.

I have been prompted to this warning because the procession has already commenced. Men are reaching this camp at the rate of one a month. So far they have been entertained for a day or two and helped on their way. This is not pleasant for men anxious for work, and if the stream increases the scattered camps will not feel able to do as much as they do now.

It should not be overlooked that the tendency in seeking work is to drift farther into the country, and that the difficulty of working back to the coast is great.

A man "on his uppers," willing to do "anything," has not the scope which he has at home, for good labor is content with 50 cents a day. I have miners working at this figure, and the work is much sought after. They work from six to five, often up to their knees in water, with only forty minutes for rest and food, under a hot sun. And it is actual hard, muscular work.

Colombia is a country of great resources and many possibilities, and far from fully developed. There are openings here, but there are more openings anywhere in America. And an American from Panama is not likely to wish to settle here in one spot to slowly and laboriously carve out a mere "good living" for himself.

From inquiry—not from personal knowledge—I gather that Venezuela is on a par with this country. Of the other South American countries I know little. But before taking a journey south an American worker will be wise if he obtains from some reliable source particulars of the conditions prevailing in the country he thinks of visiting.

W. E. WARD.

Medellin, Colombia.

A Problem in United States Coins

To the Editor of the SCIENTIFIC AMERICAN:

Here is a little problem in figures that may be of some interest to your readers. Having for many years handled the shipments of coin from this mint, I have observed many combinations. The following however is most peculiar and will give your readers something to work over. Perhaps some of your readers would give an algebraic formula for the solution. How can 200 coins of the United States (present coinage) be so divided as to total $500. Every coin must be used at least once. Coins now minted are 1-cent, 5-cent, 10-cent, 25-cent, 50-cent ($2½, $5, $10 and $20 gold).

THEODORE L. DELAND, *Shipping Clerk*.

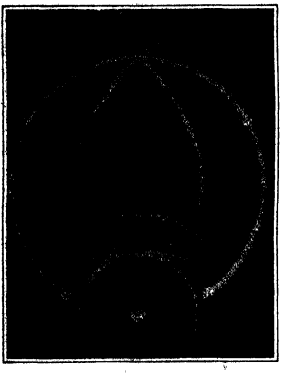
United States Mint, Philadelphia, Pa.

Halos and Sundogs

To the Editor of the SCIENTIFIC AMERICAN:

On the second day of November, 1913, there was manifested in the sky a very complete set of halos and sundogs. They were seen here in Richmond and probably in a considerable area, for several inquiries were received by the railway companies from their station agents out on their lines as to the cause of the phenomena.

I first noticed the phenomena about noon, and they remained visible several hours. The most marked object was a large circle about thirty degrees above and concentric with the horizon. It was white and about the width of the full moon. On this circle there were four bright chromatic nodes, marked on the accompanying drawing *A*, *B*, *C*, *D*. About the sun there was a marked but not unusual halo strongly chromatic at the point *E*, and gradually fading away toward each side as shown. There was a second concentric circle at *F*, also chromatic. From the point *E* tangents extended out on each side as shown. Perhaps the most unusual part of the picture was the lines *IG* and *IH*. They were white, about the same width as the large circle, and very clearly seen from *I* to *G* and *H*. Beyond *G* and *H* they became very faint, but seemed to curve in to the point *E* as shown. On the attached sketch *S* represents the sun and *O* the zenith.



A complete set of sundogs and halos.

I suppose all these phenomena are due to the refraction of light from minute particles of water or ice in the higher atmosphere, but the detailed explanation of how such peculiar lines as *IG* and *IH* as well as the tangents at *E* are produced is beyond me.

The day was beautiful, an ideal autumn day; cool and clear with a slight haze in the air and a bit of herring-bone effect in the sky at times. There were no clouds except very low down, and the geometrical designs traced in the sky were very striking. With some crude instruments Dr. Hopkins and I measured the angles as best we could, and the drawing is fairly accurate.

I shall be pleased to have you make such comments and explanations as you may wish.

Richmond, Va. E. C. L. MILLER.

[Dr. Miller may congratulate himself on having seen a most striking and rare phenomenon. On November 1st and 2nd, 1913, a large area of high barometric pressure—an anticyclone—was drifting sluggishly across the eastern half of the United States. Over extensive regions of the country the sky was lightly veiled with cirro-stratus cloud. Evidently the air at this cloud level was in a very unusual state of tranquility, making possible the occurrence not only of the common varieties of halo, which do not depend upon any particular angular position of the ice crystals in the atmosphere, but also those rarer halos which can occur only when the crystals are falling in a horizontal position. Complicated and beautiful halos were seen at many places in the States of the Mississippi Valley on the 1st, and in the Atlantic States from Maryland southward on the 2nd. The phenomena appear to have reached a particularly high state of development in southern Virginia, though those seen the previous day at points in Missouri and Arkansas were no less remarkable.

The lines marked *IG* and *IH* in the drawing, known as the "oblique arcs of the anthelion," are especially rare. The theory of these arcs has never been satisfactorily worked out, though they are supposed to be connected with striations on the faces of the crystals.

The nearly horizontal arc tangent to the lower halo at *E* is the "upper tangent arc of the halo of 22 degrees." With increasing altitude of the sun above the horizon the ends of this arc bend downward until it finally becomes an ellipse surrounding the 22-degree halo. It is then called the "circumscribed halo" and was seen in this form at several places on the dates in question.

All the halo phenomena shown in the drawing, and many others, are described in Mr. C Fitzhugh Talman's article "Solar and Lunar Halos," in the SCIENTIFIC AMERICAN SUPPLEMENT of November 16th, 1912.

It seems probable that if all the observations of the halos of November 1st and 2nd should be collected it would be found that some observers were treated to sights rivaling the historic "Petersburg phenomenon," of 1790, which has heretofore ranked as the most wonderful halo ever seen, except, perhaps, in the polar regions, where complicated halos are fairly common

We take this opportunity of thanking other correspondents who have sent us reports and drawings of these halos.—EDITOR.]

Positive and Negative Natural Laws

To the Editor of the SCIENTIFIC AMERICAN

In reading the editorial, "Positive and Negative Natural Laws," volume cx, No 2, I was impressed with the fact that the principles therein stated work out very well in our everyday life.

The good that is to come, the profits which are to result from working for a cause, for standing firm in tight corners, are not always evident. There is no positive law which says that there is a satisfactory reward for every worthy effort, credit for a scientific discovery may never be given to the right workers, the probable results of any particular research cannot always be foretold, or again there is no certain benefit which is positively obtained by all who respect and use natural laws.

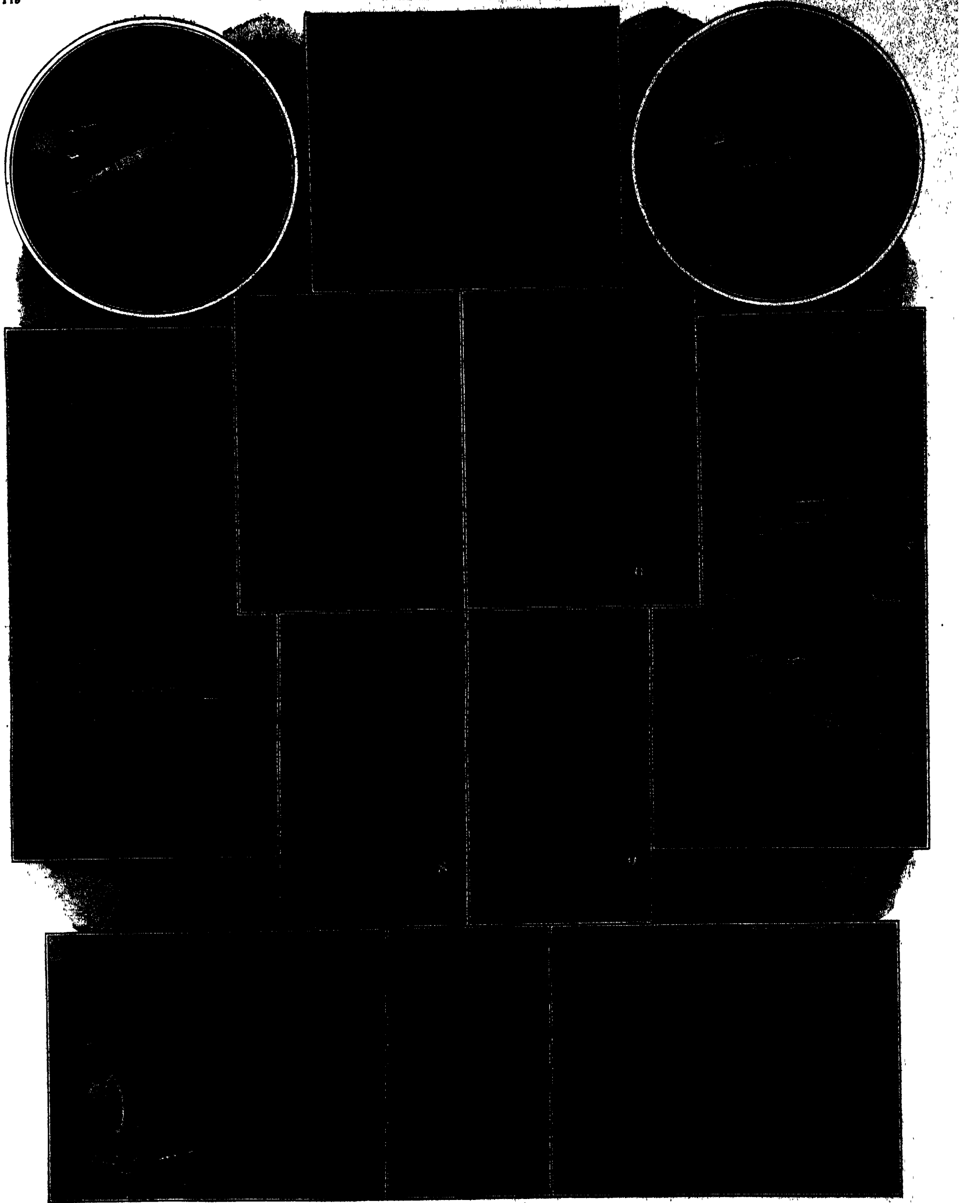
The negative causes and results, however, seem obvious. The losses, hardships, or difficulties are certain to arise from not guarding an exposed belt, not disclosing a useful discovery, not respecting natural or approved artificial laws, not conserving national resources, or other negative conduct. We do not know what electricity is, yet we are not ignorant of its existence, laws, and uses. Even the commandments are negative admonitions Certain it is then, that negative laws are of universal application; they are in fact often more powerful and useful than positive statements would be.

PHILIP E. EDELMAN

Minneapolis, Minn.

Earthquakes and the Panama Canal

DR. CHARLES DAVISON, the leading English seismologist, discusses this subject in the *Geographical Journal*, and comes to conclusions almost as reassuring as those reached by Mr. D. F MacDonald in his article in the SCIENTIFIC AMERICAN of October 18th, 1913. He gives three reasons for thinking the danger from future shocks to be slight, viz., the fact that only three earthquakes, including that of last October, have attained even a semi-destructive character in the present Canal Zone since the time of the Spanish conquest; that, as pointed out by Mr. MacDonald, the canal is remote from mountain ranges and does not traverse any important faults, so far as known; and, lastly, that even if a violent earthquake should occur it would probably have no more disastrous effect on the canal than to cause landslides from the sides of the cuttings, as the researches of Milne, Sekiya and Omori have proved the destructive vibrations of earthquakes to be confined chiefly to the surface of the ground and to extend only in a slight degree to the bottom of a deep artificial excavation. All three arguments are, however, qualified; the first by the fact that violent quakes have sometimes occurred in regions previously exempt (e. g., in the Colchester district of England, in 1884, and at Charleston, S. C., in 1886); the second by the fact that deep-seated faults, capable of giving rise to severe earthquakes, often exist in places where the surface conditions give no indication of their presence; and the third by the consideration that landslides caused by a violent earthquake, if they should occur after a prolonged period of heavy rain (a very probable event on the Isthmus), might themselves constitute a serious calamity.



1. This picture shows the method of instructing employees adopted by the New York Central Lines. It illustrates the improper way of using a jack without proper blocking. Thus used, a jack is apt to slip out and cause injury to the man using it.

2. Climbing over drawbars of cars to save walking around. A dangerous practice, since the cars are apt to be moved without warning. (New York Central Lines' method of instructing employees.)

3. Contrast this picture with picture No. 1. It shows the proper use of a jack with blocking at the top and bottom. Bolts run through the cross grain of the blocking to prevent it from slipping. (New York Central Lines' method of instructing employees.)

4. Flagging his train. The third rail makes a comfortable seat, but who protects the train? (The Pennsylvania Railroad Company's method of instructing employees.)

5. A common practice which is extremely hazardous. The employee is standing between the rails and getting on the foot-board of a locomotive as it approaches. Contrast this picture with No. 6. (New York Central Lines' method of instructing employees.)

6. Contrast this picture with No. 5. It is safer to stand outside of the rail on the engineman's side, where there is less danger of serious injury if the employee misses his footing. (The New York Central Lines' method of instructing employees.)

7. With rubber blankets the repair man guards his body or tools from coming in contact with the third rail. Exhibited by the Pennsylvania Railroad Company at the Safety First Exposition.

8. It is not necessary to go between cars in order to couple them. This is the wrong way. (The Pennsylvania Railroad Company's method of instructing employees.)

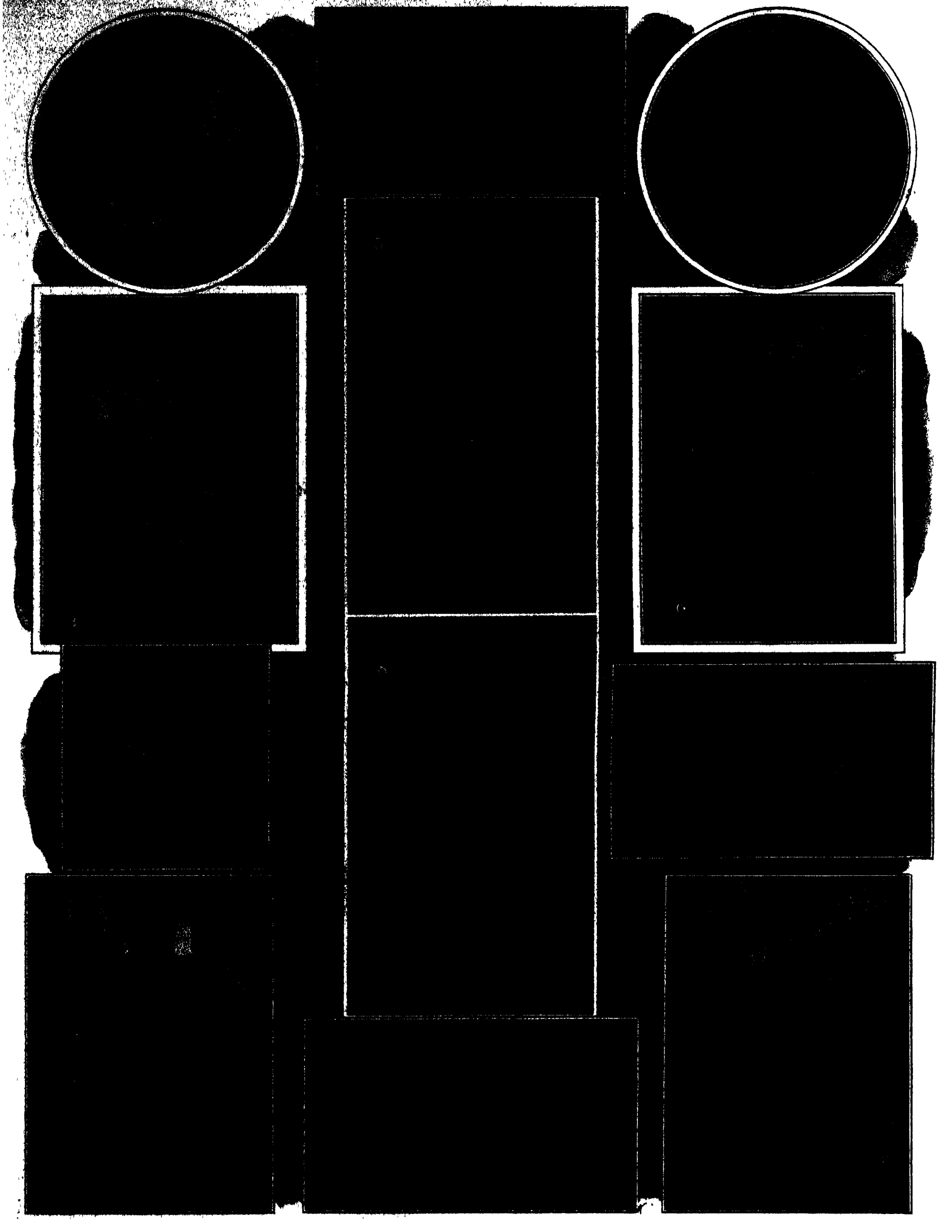
9. This is the right way of coupling cars. Contrast with No. 8. (The Pennsylvania Railroad Company's method of instructing employees.)

10. The Ferguson double derailing track target, used at the National Tube Company, Lorain works of the United States Steel Corporation. The picture shows the position of derailer when the car is approaching. The device is made double so that it may be fastened to either rail and afford protection from either direction. The word "outside" in cast letters indicates the proper position of derail when attached to rail.

11. This man takes his life in his hands. A slight jar might throw him to the tracks. (The Pennsylvania Railroad Company's method of instructing employees.)

12. Contrast this picture with No. 10. The Ferguson double derailing track target. The front trucks are completely off the rails with derailer still in place.

Safe and unsafe practices in railroading.



1. Gates swinging outward over a footway used by children in going to and from school. (Copyright, 1918, by the United Gas Improvement Company, Philadelphia, Pa.)

2. In the foundry of the New Jersey Zinc Company casting chippers use goggles.

3. The box covering the fire hose is so located that the streams cover the maximum number of buildings and the hose is carefully inclosed, but the real handle projects, so as to render serious injury to a passer-by imminent. The hazard was disposed of by disconnecting and hanging the handle under the box. (Copyright, 1918, by the United Gas Improvement Company, Philadelphia, Pa.)

4. The Benjamin safety device for stamping presses necessitates the removal of both hands from the point of danger, to trip the press before the ram starts in its downward direction.

5. The danger accompanying unlocked elevator counterweights. The valve was so located on the pump that the head of the workman adjusting it was brought directly under the counterweight and struck. Contrast this picture with No. 8. (Copyright, 1918, by the United Gas Improvement Company, Philadelphia, Pa.)

6. Guard for slotting machine in the Brown & Sharpe works. The swinging guard has a hole so that the workman may see the operating parts and still be protected.

7. Employees entering the building in a hurry formerly took the short cut over the side of the porch and in several instances injured their heads in the manner illustrated. As indicated by the dotted lines, the railing forces the employees to enter at the front of the porch. (Copyright, 1918, by the United Gas Improvement Company, Philadelphia, Pa.)

8. View of the location pictured in No. 5. A wire guard is so placed that there is no danger of a workman's being caught by the counterweight. An excellent illustration of how satisfactory guards may be made at home at very little cost. (Copyright, 1918, United Gas Improvement Company, Philadelphia, Pa.)

9. This picture shows a buzz-saw guard which was invented by one of the employees of the United States Steel Corporation. When the saw is not in use, the guard hangs down and completely covers the blade. When a board is started the guard rises against the springs *CC* and also turns on the joints *DD* and *EE*. When the board is sawed nearly through, the operator grasps the handle *F* and pushes the board through. His hands do not come near the saw.

10. Lead wires in a passageway back of oil switches. Similar hazards may be found in many offices where connecting cords of electric fans and office machines are left lying on floors. (Copyright, 1918, by the United Gas Improvement Company, Philadelphia, Pa.)

11. This illustration, exhibited at the recent "Safety First" Exposition by the Pennsylvania Railroad, shows the extreme carelessness of an employee seated on a can of gasoline.

12. Safety switch in the foundry of the Brown & Sharpe works. The truck is prevented from running off and falling on the workmen when the switch is open.

How some very common accidents are caused.

Four-Gun Turrets of the French Battleship "Normandie"

A Notable Experiment in the Mounting of Heavy Ordnance

TIME was in the French navy when the authorities favored the placing of only one gun in a turret. Theoretically, so far as the rapidity and accuracy of gun fire are concerned, that was the ideal arrangement. But French naval authorities are distinguished for the great variety and suddenness of the changes which they introduce. To-day the pendulum has swung to the other extreme, and in the four latest dreadnoughts, the "Normandie," "Gascogne," "Languedoc," and "Flandres," the French are putting four guns in a single turret—and this at a time when the two leading naval powers, Great Britain and Germany, are still using only two guns per turret.

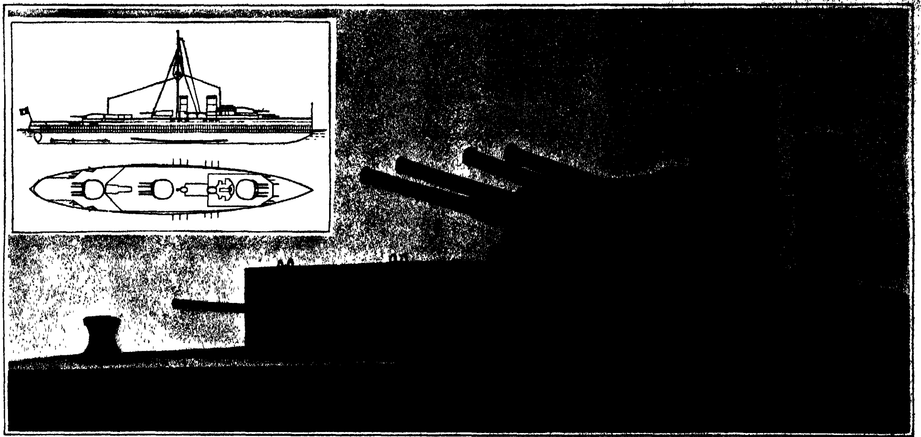
The "Normandie" class are big ships, 574 feet long, 92 feet beam, 28¼ feet maximum draught, and they displace 25,387 tons. The armament is heavy, consisting of twelve 13.4-inch guns carried in three four-gun turrets. The foremost gun is carried above a superstructure on the forecastle deck, the axes of these guns being surely not less than 36 feet above the water line. Amidship above the spar deck is the second turret; and aft above the main deck is turret number 3.

The 13.4-inch gun is a powerful weapon, 45 calibers in length and firing a shell weighing 1,433 pounds, which is slightly heavier than the shell of our 14-inch guns, with a velocity of 2,657 feet, which is slightly greater than that of our 14-inch piece; so that although of *less bore, this French gun must be of somewhat greater* power than ours.

The advantages of the four-gun turret are that there is considerable saving in weight of armor and gun carriages, and of ammunition lifts and gun-operating mechanism. Also it conduces to good shooting, for the reason that four shots fall in one place, and the work of the spotter is facilitated. It is believed that the guns are not mounted in one sleeve, but in pairs in two sleeves; but possibly the two sleeves are connected to a common elevating mechanism, in which case all the advantages of a single sleeve are secured. The theoretical disadvantage of the four gun turret is that a single heavy armor-piercing shell, penetrating such a turret, may put four guns out of commission at once.

These ships are heavily armored, carrying about 13 inches on the belt, 17½ inches on the main turret, and 10 inches on the sides of the ship above the main armor belt. The secondary battery of twenty-four 5.5-inch guns is carried as follows: Six in a battery protected by 8¼-inch armor, situated forward of No. 1 main turret, on the forecastle deck, these six guns being capable of fire dead ahead; twelve guns placed in broadside on the main deck between turrets Nos. 1 and 2 and behind 8¼-inch armor; and six guns carried on the gun deck abreast of and on the quarters of No. 3 turret. These positions are shown clearly in our deck plan of the ship.

These four vessels are to be turbine-driven on four shafts at a speed of 21.5 knots. They will be fired with coal and oil. The success of these four-gun turret ships will be watched with great interest in naval circles.



The "Normandie," one of four French ships, of 25,387 tons and 21.5 knots. Armament: Twelve 13.4-inch guns in three turrets, carrying 17½-inch armor; twenty-four 5.5-inch guns, protected by 8¼-inch armor.

The first battleships to carry four guns in one turret.

Fighting Grasshoppers in Uruguay

PEOPLE living in Kansas, Utah, and other parts of our great western plains have by no means forgotten the devastation and desolation caused by the vast hordes of grasshoppers which have swept over the country in former years. Similar pests have visited destruction on the north coast of Africa and on the rich pampas of South America.

Some recent successful efforts at fighting this plague are described in *Kosmos* by L. Geret of Antwerp as follows:

"As soon as the little creatures hatched from the eggs deposited in the earth by previous swarms are able to hop, and even before they can fly they exhibit the migrating impulse. The habitat of this Argentine plague is in the north, near the Bolivian boundary; from there the swarms overflow the rich provinces of Santa Fé, Entre Rios, and the Republic of Uruguay. In dry weather the insects lay their eggs *en route*, and pursue their career of destruction to a point south of Buenos Ayres, soon after which they expire. By January the swarm issuing from the eggs has reached maturity. . . . When at a given time all the "hoppers" of a locality set themselves in motion toward the same direction is the moment chosen for fighting them by the ancient method of the country. Sheets of tin are bound together so as to stretch continuously for many kilometers, forming barriers whose smooth sides it is impossible for the insects to scale.

"Every tree near this tin barrier is likewise provided with a tin 'cuff' to prevent its being used as a bridge. The current is checked at the barrier and begins to flow along its side. Near the barrier at spaced distances deep holes are dug and surrounded by tin barriers placed at such an angle as to form a diminishing passageway or conduit to the mouth of the hole, into which the stream of insects flows steadily till it is full. As each hole is filled it is covered with earth and stamped down and fresh holes are made.

"Naturally only a small proportion of the insects can be destroyed by this simple means. The others increase in size—many reach a length of 8 centimeters and rise into the air like a dark cloud and fly away to seek food. One evening, at Fray Bentano's on the Uruguay the writer helped frighten away a swarm which had even from afar the threatening aspect of the smoke from a conflagration, had then flown over the river, 7 kilometers wide at this place, and was about to settle on the beautiful flower-decked gardens of the casino of the Liebig Company. With hastily concocted banners, with whistles, trumpets, bells, tin-pans, fire-locks, a deafening gong, and an unearthly pandemonium, the great body of the hungry swarm was driven away to fall on more distant fields. Yet enough of them remained with us to rob many a tree of its crown of leaves, and the procession of the flying insects seemed almost interminable, offering a noteworthy spectacle. . . . The extent of such swarms in flight has been estimated to be at times dozens of kilometers in length and many kilometers in breadth.

"An indefatigable investigator of the Pasteur Institute in Paris, Felix d'Herelle, has succeeded by the artificial propagation of an insect-disease in almost annihilating the most formidable swarms of this pest in the Argentine. During a stay on the Yucatan Peninsula in 1910 this well-known bacteriologist studied a malady then raging among the grasshoppers there. Dr. Roux, the director of the Pasteur Institute, presented the results of his observations before the French Académie des Sciences.

"According to this report a certain bacillus (*coccobacillus acridiorum sp. nov.*) has such an effect on the grasshoppers that they perish within [illegible] hours. The intestinal content of the insects is then found to be an almost pure culture of the bacillus. M. d'Herelle expressed the opinion that the insects could be exterminated by any artificial spread of this 'epidemic.' M. Gallardo, the director of the National Museum of Buenos Ayres, was staying in Paris at the time, and induced the Argentine Bureau of Agriculture to invite the French investigator to test his process practically in South America. M. d'Herelle accordingly caused a swarm of grasshoppers in Santa Fé to be surrounded by a palisade in order to study the effects of his epizootic cultures within the inclosed space.

"These culture of bacilli were dissolved in water and sprinkled over a small portion of the maize which the insects had begun to devour. The malady spread with extraordinary rapidity. By the end of two days dead grasshoppers were found in every corner of the field of experiment; after the sixth day there were none left alive.

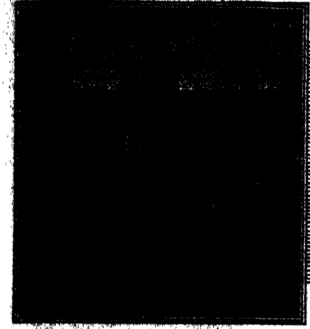
"Experiments on a large scale were attended by a like success. One liter of the culture liquid was spread over a field. After 5 days countless dead insects were found over the whole extent of the field of 25 hectares. The fatality continued on following days and spread through the vicinity. The speed with which the malady spreads is amazing. Only a few days after the start of the infection it was found to have extended to [illegible] kilometers distance from the original spot, being in every case carried by the winged insects, which are capable of covering 30 kilometers in a day.

"Other varieties of grasshoppers were also attacked by the disease, so that the hope is justified that it will prove an effective agent against this terrible plague in other localities."

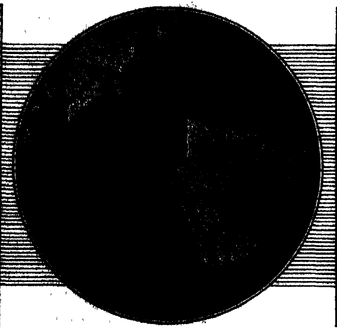
Safety in Steel Works

The Scientific American's Associate Editor Sees How Employees Learn Caution by Hunting Dangers

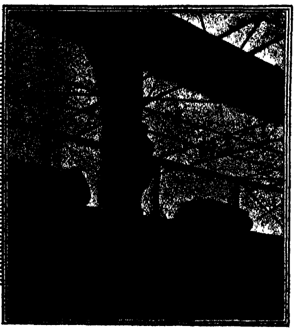
By A. Russell Bond



The crane man used to have to climb up the lattice work to his cab.



Railed stairways and platforms with safety treads now lead to the crane cab.



The first attempt at safety for the crane man was a wooden ladder.

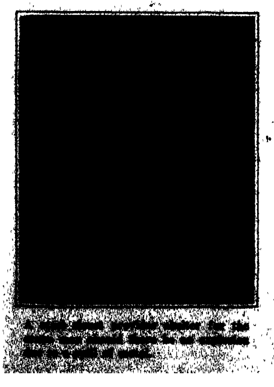
ANYONE who thinks that the safety movement of which we hear so much these days consists merely in an agitation for the adoption of safeguards and "fool-proof" machinery, is far behind the times. Probably that individual also thinks that the "fool" against whom the machine must be "proofed" is an ignorant foreigner. But that is another mistaken notion. The man who gets hurt is the careless man. He may be careless by nature or by design, and to neither of these classes does the foreigner belong. The very newness and strangeness of his surroundings makes him cautious. The man who makes the most trouble, not only for himself, but for his fellow workmen, is the one who thinks it smart to take a chance, the one for instance who does not consider himself or his fellow a good railway man unless he can stand between the rails before an approaching locomotive and step upon the footboard just as he is about to be struck. He is a good sport and takes a chance on what he feels is a pretty sure thing. Nevertheless, it is a game of chance and stakes are very high.

A man of such disposition is most ingenious in devising methods of self destruction or injury, and the mere provision of safeguards cannot cope with his propensity to mischief. Something must be done with the man as well as with the machine, and so now the more progressive safety organizations lay great stress on educating the careless employee to a new attitude toward the dangers that inevitably lurk about him. The best way to learn a thing is to teach it. Hence, it is the custom to make safety instructors of the men themselves, as in that way they will learn what the safety movement is, and how best it may be furthered.

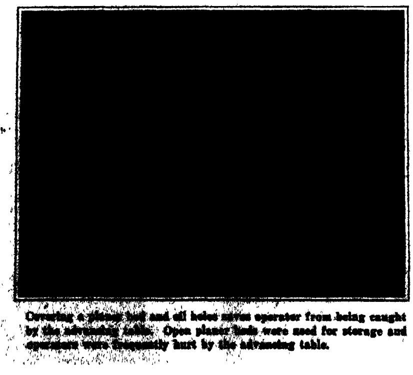
An excellent illustration of this method may be found in the organization of the United States Steel Corporation. The safety idea permeates the whole organization from the highest official down to the workingmen themselves. First of all there is the Steel Corporation Safety Committee, consisting of an officer of the Steel Corporation as chairman and seven other members representing the largest subsidiary companies. This committee meets quarterly to study serious accidents and makes recommendations against further occurrences. It conducts its inspection by having an inspector of one company inspect the other company's operations. All the inspections are made personally. Second, there are central safety committees of the subsidiary companies, made up of important officials from each of the plants, mines or railroad divisions, which conduct inter-mill inspections and meet monthly for conference and recommendation of safety devices. Third, there are plant safety committees which meet monthly, weekly, or in some cases daily. Fourth, there are the department and special committees, made up of foremen, master mechanics and skilled workmen, who meet weekly or monthly as the case may be. And finally, there are the workmen's safety committees, usually made up of three members of the rank and file of the mill. These members are changed periodically, so that eventually every man in the works will at one time or another have held a position on one of these committees.

During the year ending December, 1912, 4,678 men served on the various committees, and probably the greatest service was done by the last two committees, because they were made up of those men who were studying their own personal risks, trying to find trouble before trouble found them. It is the policy of the company to encourage the men to make suggestions by means of rewards. As an illustration of the value that is attached to the employees' own recommendations, we may take the case of the guards placed over circular saws. When the foreman of the shop is informed that he must place a guard over the saw and a certain standard type of guard is recommended to him, he is quite apt to look with contempt upon the device and criticise it as being of little value. "All right, John," says the safety inspector, "you are an ingenious fellow. Why don't *you* get up a safety device that is *really safe*?" And so John thinks the matter over, and in a day or two suggests a design for a new guard which the safety inspector praises highly and is glad to accept; for although the device may not be as good as the one originally recommended, it will be scrupulously used, and the foreman will see that all the men under him use it too. Far better is a poor device faithfully used, than a good device employed under protest. But the result of this policy of letting a man build his own safety device has resulted in the designing of some very clever apparatus. With the ordinary guard there is nothing to prevent the operator from having his thumb cut off as he follows up the work to the saw. One ingenious foreman, realizing this defect, provided the bottom of the saw guard with teeth or notches, by which the work could be pushed up to the saw. This safety device is illustrated on another page.

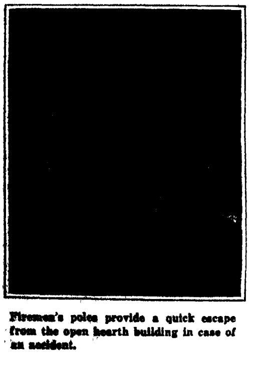
The writer recently had occasion to visit the works of the Illinois Steel Company at South Chicago, and was struck by the "safety first" atmosphere that pervaded the whole works. Safety signs in five languages were set up at all points in the works where there was a possibility of accident. Not only that, but the men themselves seemed imbued with the safety spirit and enthusiastic in their support of safety methods. Last spring an accident occurred in one of the open hearth buildings, which illustrated not only the efficiency of the safety precautions provided against such an accident, but also the spirit of the men. A huge ladle containing fifty tons of molten metal was being taken down the building by means of a traveling crane. One of the bearing boxes of the winding drum of the crane broke, causing the drum shaft to tilt and throw the gears out of mesh. Immediately the tackle on one side of the ladle slacked away, permitting the molten steel to pour out upon the floor below. A spill of this sort



A [illegible] shelter for the [illegible]



Covering a planer bed and all holes saves operator from being caught by the advancing table. Open planer beds were used for storage and operators were frequently hurt by the advancing table.



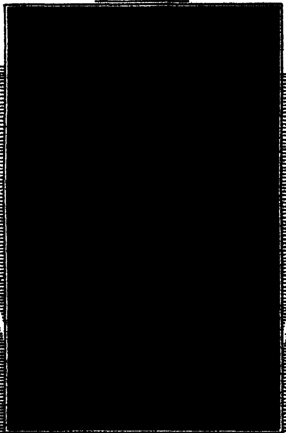
Firemen's poles provide a quick escape from the open hearth building in case of an accident.

is invariably attended by an explosion, and not a second must be lost in jumping out of the way to avoid being burned to death. To provide for just such an emergency, the outer wall of the building had been provided with window openings all along the pouring level, and these windows were protected on the outside by means of wooden hoods Four or five men were on the pouring platform when the accident occurred, and immediately they leaped to safety through the opening. (See our cover illustration.) The crane man also was in immediate danger and had to act instantly. There was not even time to stop the crane. He leaped for a ledge above the craneway and dodged through one of the many windows provided for just this purpose, to a runway at the outside of the building. It was a narrow escape; but the crane was still running down the mill, pouring out a stream of liquid fire, and if it were not stopped, would soon reach a number of men who were at work in the "pit" with no chance of escape; also if the crane continued, it would eventually strike the end wall of the building and doubtless go to smash or destroy the wall. Mindful of these dangers despite his own harrowing experience, the crane man ran along the runway outside of the building until the first flare of the explosion had subsided. Then he dodged through one of the windows ahead of the crane, jumped into the cab as it came along, and brought it to a stop His presence of mind saved many lives and valuable property. He was rewarded by a "safety first" banquet and a raise of pay Although the men who were on the pouring platform did not hesitate an instant to take the leap, nevertheless after they had undergone the experience, they realized that a jump into space required some courage and was not without danger. Accordingly, one of them recommended that the openings be provided with firemen's poles, down which the men could slide. This recommendation was immediately adopted, and one of the accompanying photographs shows how the hooded openings now look with the pole equipment.

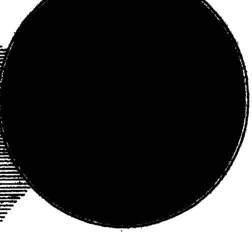
A funnel on the mouth of the "mud gun" prevents chopping off of toes and heels.

The windows of the saw-tooth roof are safely cleaned from the trolley that runs all around the building.

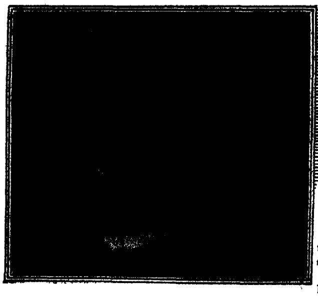
A handle on the hook saves the fingers.



Castings are broken up with a skull cracker picked up by an electromagnet and dropped upon them. To stop flying fragments a stockade of pipes filled with concrete has been set up. The value of this stockade is shown by the dents in the pipes.



This hook will not release when cable is slack.



These gears used to be uncovered and were a constant menace.

Now the bevel gear is almost completely inclosed in a sheet steel casing.

So sudden is the explosion from a tipped ladle, that sometimes the crane man has no opportunity to dodge out of the building. Accordingly the cabs are provided with steel compartments in which the operator of the crane may shut himself for protection against the intense heat. This gives him a chance of escape unless the heat is so prolonged as to bake him inside of his shelter.

Ladles are usually tapped by withdrawing a stopper. Formerly the stoppers were suspended by an ordinary crane hook, but on a couple of occasions as the stopper was being lowered it struck on the rim of the ladle, and as it hesitated there an instant, the slack in the hoist cable allowed it to become unhooked. One of the employees suggested a "pig's tail" hook, which has proved entirely satisfactory, as it prevents the suspended load from going over the point of the hook. Another type of safety hook designed by one of the men has a handle at the back by which it may be operated without danger of catching the fingers between the hook and the load.

Hundreds of little devices of this sort have been developed by the workmen's safety committees. One of the illustrations shows an improved mud gun, developed at the works of the National Tube Company in Lorain, Ohio. It is a machine with which balls of clay are packed into the tapping hole of the furnace to close it after the furnace has been tapped. The clay balls are dropped through a hole in the casing of the gun in front of a plunger which [illegible] opening. It used to be that if a clay ball [illegible] in the hole, the operator would push it down with his foot. As a result many a heel or toe was cut off by the plunger because the man pushed his foot in too far. To overcome this, a funnel is placed on the mouth of the mud gun, making it impossible for a man to push his foot in far enough to get it caught.

While the workmen supply many safety suggestions, most of them come from the official safety inspectors. Herewith is a set of three pictures from the Carnegie Steel Company's plant at Homestead, Pa., illustrating the improvements that have been developed in providing access to the crane cab. Originally the operator of the crane was obliged to climb the steel lattice work of the columns in order to reach his cab. This proved a dangerous practice and so ladders were provided, as shown in another picture. But this still required a man to be pretty much of a monkey in order to reach his cab, and eventually, steel stairways and platforms with friction treads were provided, so that a man could reach his crane cab in perfect safety. The platforms also are of use in making repairs upon the crane.

In a plant like that at Gary, Indiana, which has been built since the safety movement was started, safety provisions were made from the very start. But in the older plants an enormous outlay was found necessary to bring them up to present day safety standards. One of our illustrations shows a trolley for window cleaners

(Concluded on page [illegible].)

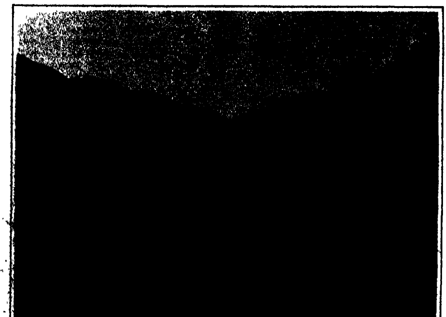
Let the Sun Supply Hot Water

T[illegible] on sunny days, but also, by means of a cleverly devised tank, will conserve the heat over a number of dark days. This is made possible by a packing around the tank similar to that in a fireless cooker. Not only hundreds of homes in the West are thus equipped, but a number of public buildings, notably playground and school buildings, in California make use of this system to supply hot water for shower baths without cost. After the plant is paid for, there are no further charges. The photograph shows one of the largest of these public installations, a 500-gallon tank heated by three night-and-day solar heaters on the roof of the playground building in Exposition Park, Los Angeles. The "chimney" on this structure is in reality a screen for the tank, which is set upright in the attic, projecting through the roof. The heating coils of galvanized iron pipe are in the three glass-covered boxes, exposed on the southern face of the roof. These are connected with the tank, which in turn connects with the showers. No artificial heat is needed. For use in the Eastern States, the system is available the greater part of the year, while in winter the heater coils are drained to prevent freezing, and an auxiliary piping system that joins the furnace or other house-heating device is installed. Half a dozen playgrounds and four or five schools in California have been thus equipped recently, while the domestic installations have been in successful use for years. Even apartment houses have made use of this economical method of obtaining plenty of hot water at any hour of the day or night.

Solar heater on the playground building in Los Angeles furnishing hot water for shower baths.

The Highest Dam in the World

THE United States Reclamation Service is blocking the Boise River canyon, at Arrowrock, with a dam 350 feet high. This will be the highest dam in the world. It will have a length of 1,075 feet at the top, and will contain 530,000 cubic yards of material. During construction the waters are being diverted through a tunnel running around the dam. The tunnel is 487 feet long and measures 25 by 30 feet. It is large enough to pass the whole of the Boise River. The accompanying photograph shows the water pouring out of the tunnel. On the right, near the top of the picture may be seen the excavation for the spillway, which shows to what a height the dam will be carried.



Building the Arrowrock dam across the Boise River; the highest dam in the world.

German Gasoline-Electric Road Train

By Our Berlin Correspondent

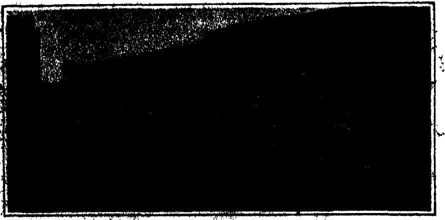
A REMARKABLE gasoline-electric road train has recently been introduced in Germany which comprises a power car and ten trailers each of 5 tons capacity.

The power car carries the generator set, viz., two Daimler motors of 125 horse-power each, driving a dynamo installed in the center. The current is transmitted to the electric motors actuating each of the wheels of the power car and trailers. The armatures of these motors are arranged in parallel, and the inductors in series; the former derive their current from the main dynamo, whereas the latter are fed from an exciter machine which at the same time serves to excite the main dynamo. The field regulator of the main dynamo controls the tension of the armature, and accordingly, the speed of the train. A loop circuit allows a perfect uniformity of tension to be insured in all motor armatures. The motor fields are excited by a special "traction regulator," inserted into the exciter circuit, and the direction of travel is controlled by reversing the excitation of the motor fields.

The electric apparatus and instruments are arranged on the motor car, above the dynamo, so as to be readily accessible.

The steel rims of the wheels are 1.2 millimeters in diameter and 250 millimeters in width. Thanks to the identical construction of all the trucks, the number of exchange parts is reduced to a minimum. Chain transmission has been used to connect the trucks with one another, and the inside brakes formerly used have been replaced by outside brake shoes acting directly on the circumference of the wheels, thus greatly facilitating the superintendence of the brakes.

The weight of the power car in full working order is 9 tons, and of each trailer, 3 tons, or 39 tons altogether. The ratio between the carrying capacity and the net weight thus works out at 50 ÷ 39 = 1.3, which is 30 per cent more favorable than in the case of heavy load vans. The mean traveling speed is 12 kilometers (7.5 miles), and the maximum speed 16 kilometers (10 miles) per hour.



Gasoline-electric road train of 50-ton capacity.

How the Ostrich Rancher Travels

THE rancher in California or Arizona who goes into the business of raising ostriches can travel behind a team of these huge birds or use one as a saddle animal. The ostrich shows remarkable speed as a trotter, and a pair of them attached to a light sulky can make a mile in pretty close to two minutes. It will be observed that the light rig is equipped with a third wheel to take part of the weight from the team. The ostrich as a mount is almost as speedy, and carries a man easily.

Ostrich trotting team. Note the third wheel.

A Unique Emergency Power Plant

WHEN a manufacturing plant is confronted with the problem of replacing an old, inadequate battery of boilers with a new one of greater capacity, it is not a simple matter to make the change without interrupting operation.

This condition was met most ingeniously when it became necessary for a company of Philadelphia, Pa., making textile machinery and centrifugal hydro-extractors, to increase its source of power supply An estimate from the local company showed electric power to be of prohibitive cost. The idea of utilizing locomotives for the purpose, while novel, at first thought, bore the elements of sound judgment.

The location of the plant, on the main line of the Pennsylvania Railroad, made feasible the storage of locomotives on a long freight siding.

It remained a problem, however, to get locomotives of the proper capacity, for in these days of heavy railroading, small engines are rather difficult to obtain.

Two "American" type locomotives were finally obtained at a very reasonable rental. While they were doing service, the old battery of two boilers was replaced with a 462 horse-power boiler, stoker-fired by an automatic stoker of the five-retort type; the furnace is fitted with an extension grate, giving enough grate area to insure absolute combustion of the fuel, without having to have a brick arch

The process of locomotive boiler substitution was simple, but effective. The two old locomotives, whose connecting rods and valve gears had long been disconnected, were hauled to a convenient point on the siding, after their tenders had been uncoupled; their throttle valves were closed, and a connection piped from their auxiliary domes, over the fireboxes, to the main steam lines in the plant.

Their positions, back to back, with an elevated platform erected between them, allowed sufficient space for two firemen, and a coal supply that could be replenished without interrupting the service.

As a matter of fact, this means of steam supply is hardly economical enough to warrant its retention for a protracted period, since the amount of coal consumed per horse-power hour is far greater than the average manufacturing plant can afford; but there is no question that the money for the excessive coal consumption, in addition to the moderate rental, and a few dollars more for labor, are well spent when a continuous, liberal steam supply is assured, that keeps the plant in operation during the installation of the new boilers, and whose connection with the main steam supply can be made in a short time at night, without stopping operations

The Human Body in Action
How Science Helps

The phases of a springboard acrobatic somersault.

EVER since 1896, the year in which the historic Olympic games were reinaugurated on a scale far grander than that conceived by the ancient Greeks themselves, there has been an unquestioned increase not only in the popular interest in athletics, but in scientific interest as well. In France physicists have applied scientific methods to the study of athletes in action with astonishing results. To be sure, this is nothing new. Years ago Muybridge published a series of photographs taken of men and animals in action, which are still regarded as classic in their way. But since Muybridge's day, apparatus and methods have improved, and it is now possible to record for future study athletic movements which it would have been difficult indeed to analyse twenty years ago.

Probably the foremost of Muybridge's successors is the distinguished Prof Marey, whose interesting and valuable work has been so frequently commented upon in the columns of the SCIENTIFIC AMERICAN. The accompanying pictures were made in accordance with his methods by Prof. Demeny. The apparatus used has been improved by Demeny and used by him at the French Academy for Military Sports in Joinville-le-Pont.

As our pictures show, the athletes are photographed, not upon a moving picture film a thousand or more feet in length, but upon a single plate. A black background is employed and the subjects are brightly illuminated, with the result that they are very sharply defined. The movements can be analysed into as many separate stages as may be desired, so that the result is not unlike a very slowly moving cinematographic film. Because the pictures are all taken upon a single plate, they lend themselves admirably for study and instruction. It is perfectly apparent that from pictures such as those which we publish, the athlete can learn much. He sees at once at what particular point of a movement he assumed an incorrect position, and why it is that he runs, walks, leaps, or fences inefficiently. Hence, photographs such as those which we reproduce have a very practical value. At the Joinville school, they are used to record and register the physical conformation and development of the pupils before, during and after training. The studies thus obtained are applied in choosing and instructing the gymnastic staff of the French army.

Any one of the pictures made in accordance with the Marey-Demeny system constitutes what may be called a "graph" or chart. It ought to be possible for an athlete to compare his photographic self, reproduced perhaps a dozen times on a single plate, with a standard "graph," and thus determine how he compares with a crack runner, fencer, or gymnast. "What am I doing wrong?" is a question that every athlete puts to himself. Even his trainer cannot always answer that question correctly; the movements are so very numerous and so very rapid that only the general effect produced can be criticised. In some games, such as in football or tennis or fencing, the timing of each movement is of vital importance. By studying photographs of himself, the player or fencer will learn, first, what is the minimum number of movements required and then the trick of making them in the minimum time.

It is obvious that the moving picture camera will accomplish much the same result as the apparatus of Professors Marey and Demeny. But on the other hand, a moving picture machine and its films are expensive. Besides, it is not easy to run a film slowly enough to enable an athlete to analyse his movements, because the highly inflammable celluloid of the film may catch fire if it is held too long before the electric arc.

Military Aeronautics in the United States

MILITARY aeronautics is extensively discussed in the report of the Chief Signal Officer, United States Army, for 1913, just published. This report emphasises a fact of which the public is probably not generally aware, viz., that the number of civilian aviators in this country is fast diminishing, and in the event of war at the present time it is doubtful whether a score of men capable of making flights useful to the army could be obtained from civil life. Hence, the urgent necessity of increasing the aeronautical branches of the army, navy, and national guard. The Signal Corps at present

Spontaneous Combustion

THE term "spontaneous combustion" is generally connected in the public mind with coal, green hay or charcoal, but its application is much more extensive. One rather rare catastrophe often ascribed to this cause is the mysterious explosion of a flour mill. In reality this is due to the accidental spark ignition of an explosive mixture of flour dust and air. The mixture must be just right, yet once in a long time the dust-laden air of a mill meets the requirements and is ready for a spark from the machinery to start the trouble. [illegible] of dust in the region of the spark [illegible] almost instantaneously, and an explosion results.

[illegible] coal dust in air can be exploded with [illegible] as was shown by the recent Pittsburgh [illegible] of the Bureau of Mines.

[illegible] that spontaneously [illegible] when exposed to the air—or oxygen—and the [illegible] difficulties are annoying. Zinc [illegible] and another even more spectacular is "pyrophoric iron"—pure iron dust prepared by the reduction of iron oxide in an atmosphere of hydrogen. This curious variety of iron is sealed in the glass tube in which it is prepared—free from air—and when the tube is broken the instant combination of the iron and oxygen is accompanied by a flash of flame.

Of vastly greater concern to the public is the spontaneous combustion of coal. In large masses coal slowly unites with oxygen, producing some heat, and if this heat is not rapidly conducted away it acts as an accelerator to further oxidation. Since raising the temperature 18 deg. Fahr. doubles the velocity of most chemical reactions one can appreciate the cumulative effects of oxidation in large masses. In a small pile of coal this heat is slowly developed and radiated so readily that no rise in temperature is noticed. In a large pile of densely packed coal, however, radiation is restricted so that the temperature rises and, under favorable conditions, reaches the ignition point.

Coal dust exposes more surface than the same weight in lumps, so it is a source of danger, especially when mixed with lumps in such a way that air passages extend into the interior of the mass. When this circulation of air in the pile is just sufficient to support the oxidation, but not enough to carry away the heat developed, spontaneous combustion results. The Bureau of Mines sent out 2,000 letters of inquiry to large coal consumers of the United States, and out of 1,200 replies, 200 reported cases of spontaneous combustion. A great many such fires have occurred in the large storage piles at Panama. These are mostly Pocahontas, which produces an abnormal amount of dust.

The Bureau of Mines makes the following recommendations:

1. Do not pile bituminous coal so that any point in the interior will be more than ten feet from an air-cooled surface.

2. If possible, store only lump.

3. Keep dust out as much as possible, therefore, reduce handling to a minimum.

4. Pile so that lump and fine are distributed as evenly as possible; not, as is often done, allowing lumps to roll down from a peak and form air passages at the bottom.

5. Rehandle and screen after two months. Even if considerable heating has taken place this handling will cool it off and combustion seldom takes place afterward.

6. Keep away external sources of heat even though moderate in degree.

7. Allow six weeks seasoning after mining before storing. This allows the surface of the lumps to become less liable to oxidation.

8. Avoid alternate wetting and drying. Eastern coals may be stored under water in safety without loss. Western coals take up too much water under such treatment and much heat is lost in steaming out this absorbed water.

9. Avoid admission of air to interior of pile through interstices around foreign objects such as timbers or irregular brick work; also through porous bottoms such as cinders.

10. Do not try to ventilate by pipes as more harm is often done than good.

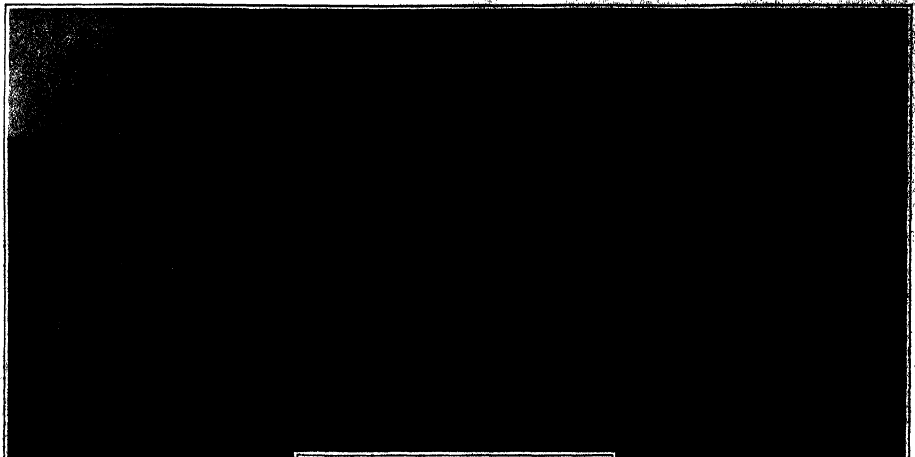
Charcoal, because of its great porosity, is peculiarly liable to spontaneous combustion. Its use as a deodoriser depends on its wonderful power of absorbing gases and experiments have shown that after exposing to a white heat for three hours charcoal can still retain a small amount of absorbed gas. Its enormous inner surface for contact with oxygen is often its own destruction. Charcoals made from some woods ignite as soon as exposed to the air. In 1911 there were sixty-four reported fires in the transportation of charcoal in this country alone, and of these all but one were apparently due to spontaneous combustion.

A farmer's barn stored with green hay is always in some danger. Unless the juices were properly sun-dried considerable fermentation takes place in the mow and the heat generated facilitates oxidation. The mass of hay is often so great that in the interior heat is developed faster than it is conducted away and then the ignition point is approached and possibly reached.

What About the Wheels?—It is interesting to note that in nine cases out of the proverbial ten, the wheels—most vulnerable parts of all—of armored automobiles are left practically unprotected. One well-directed shot might very easily so cripple the average armored car as to place it completely at the mercy of anyone with real or fancied reason to accomplish its downfall. The necessity for properly armoring wheels as well as bodies is very real and very earnest and cannot well be overlooked.

Safety in an Automobile Factory

Methods That Have Produced a Sixty Per Cent Reduction in Accidents

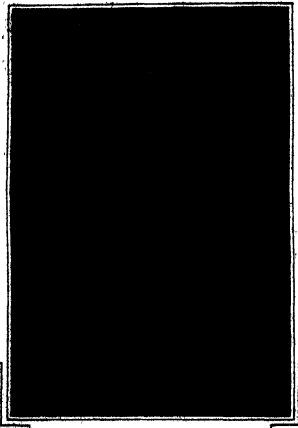


Forced draft apparatus for drawing steel particles from the grinding room.

"SHOW me the conditions for an accident," says a prominent safety official, "and I will show you the accident." He is associated with the United States Steel Corporation, which employs so many men that almost every kind of an accident that might occur has occurred at one time or another in its history. When a possible source of danger is pointed out to the foreman of a shop, he is quite apt to laugh at the idea of any risk. "Why," he will exclaim, "we have worked here twenty years without an accident." To this the safety inspector can almost invariably reply that such an accident did once happen in such and such of their own plants, and there is no reason why it should not occur here at almost any time. The need of safety precaution is more apparent in a large corporation employing hundreds of thousands than in factories employing but a few hundred. Yet it is no less real in the latter than in any one of the plants of similar size in the big corporations. If safety precautions pay in one, they should pay in the other.

This high-speed machine may be stopped instantly by the emergency brake shown at the right.

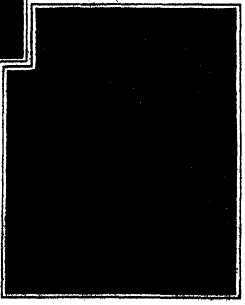
We love to dwell on the more noble, humanitarian side of the safety movement. But it is not merely a question of philanthropy; it pays in dollars and cents. Employers must not forget that it costs something to break a new man into the work. Every workingman is an asset to the company, and if he be incapacitated by accident, the employer must figure among other losses that of the money invested in this man's training; for in order to replace him, he must go through all the trouble and expense of breaking in a new man. This is so in almost any line of work, but particularly in those factories where the work is of a highly specialized character.



The hammer cannot drop until the workman has removed his hands from under the safety cross bar.

By way of illustration, we have reproduced on this page some of the safety precautions used in the factory of the Packard Motor Car Company, at Detroit, Michigan. The factory is by no means a small one. In fact, it is one of the largest automobile factories, employing about ten thousand men. But in point of size, it is not to be compared with the United States Steel Corporation, for instance, which employs about two hundred thousand men. Nevertheless, the Packard Company has found that it pays to develop an elaborate safety system. At the head of its Bureau of Safety is an expert machinist, whose whole time is employed in installing protective devices, and educating workmen in precautionary measures. Every day he and his assistants make the rounds of the shop, hunting for uncovered flywheels, exposed gears, unprotected belts, projecting set-screws, and all other possible sources of danger to workmen.

Primarily, the shops were designed with a view to giving each machine more than the usual amount of working space, and plenty of daylight. One of the principal sources of danger in the ordinary machine shop arises from the crowded condition of the rooms, and the cluttered condition of the floors. Give a man plenty of room and plenty of light, and not only will he be less liable to injury from contact with moving parts of the machine, but his improved surroundings will react upon the work that he puts out. So far over five hundred different devices have been installed in the plant to do away with risk. These devices consist not only in the customary guards, but in other precautions, a few of which are shown in our illustrations. An elaborate forced draught system has been installed for drawing off particles of steel from the grinding room, so that this room is free from injurious dust. In the body plant, the aluminium bodies are prepared for paint by a blast of fine steel shot. So powerful is this blast that it would tear the toughest oak frame to shreds. Hence the workmen must be protected, and they are furnished with heavy helmets which drop over their shoulders. One of the photographs shows a heavy hammer in the forge shop, fitted with a safety device to prevent a man from having his hand mangled. A safety cross bar projects across the table of the machine. To introduce the work the operator has to lift this cross bar. Then the hammer will not drop until the workman has removed his hand, allowing the safety bar to strike the machine base. Another special safety device is an emergency brake for a high-speed lathe. In case of accident, the machine can be checked instantly by the use of this brake.



In the body plant the workmen are protected by heavy helmets from the blast of steel shot.

The Bureau of Safety at the Packard plant has been working only two years, but in that time the number of accidents in the factory have been decreased 60 per cent. Do safety precautions pay?

The Strangest Form of Cloud: Mammato-cumulus

THE accompanying photograph, which is from the collection of the United States Weather Bureau in Washington, is probably the most remarkable picture ever made of the rare variety of cloud known to meteorologists as *mammato-cumulus*. It was taken by Mr. L. C. Twyford, at Bartlesville, Oklahoma, who reports that about 45 minutes before these clouds were seen a destructive tornado occurred some 20 miles away in the direction from which the clouds came. Clouds of this type seem to be especially associated with a severe storm. They were seen by Prof. H. C. Frankenfield at St. Louis in connection with the tornado and just before it did so much damage in that city on May 27th, 1896.

The earliest description of mammato-cumulus appears to have been that contributed by the Rev. Charles Clouston to Dr. Mitchell's "Popular Weather Prognostics of Scotland" (1863), and subsequently in a work by himself on the same subject. In the Orkneys, where he resided, it was well known to seafaring men under the name of "pocky cloud" ("pock" or "poke" being a dialect term for a bag), and was regarded as a sure sign of a coming storm. Clouston compares it to "a series of dark cumulus-looking clouds, like *festoons of dark drapery*, over a considerable portion of the sky, with the lower edge well defined, as if each festoon or pock was filled with something heavy; and generally one series of festoons lies over another, so that the light spaces between resemble an Alpine chain of white-peaked mountains."

The characteristic form of this cloud is expressed by others of its numerous names, as "festoon-cloud," "mammiform cloud," "udder-cloud," and "sack-cloud." In Lancashire the festoons are known as "rain-balls," and are regarded as a sign of rain.

The peculiar feature of mammato-cumulus is that the rounded protuberances appear to project downward from the general cloud layer. Some writers have suggested that they are not really projections from the latter, but separate rounded clouds, having a more uniform sheet of cloud above them. Various other explanations have been offered.

From Monthly Weather Review. Photographed by L. C. Twyford, Bartlesville, Okla.

Mammato-cumulus clouds.

This picture was taken looking up at an angle of 85 degrees; i. e., nearly perpendicular.

A Portable Field Searchlight

By the Berlin Correspondent of the Scientific American

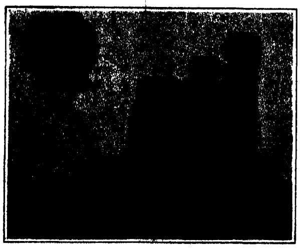
THE experience of recent wars has strikingly shown the benefit to be derived from skillfully operated electric searchlights. With the probability of night operations increasing in the wars of the future, the equipment of field armies with searchlights suitable for military uses has become a necessity. Now all the excellent systems adopted in actual practice, are designed to be conveyed on cars and therefore are difficult to handle on mountainous ground.

The Messrs. Siemens-Schuckert Works, which has taken such a prominent part in developing the electric searchlight, has succeeded in producing a portable field searchlight outfit, likely to comply even with the most exacting requirements. While using a very efficient parabolic glass mirror 35 centimeters (13.8 inches) in diameter of a range of 1,000-1,500 meters (3,281-4,921 feet) this outfit, inclusive of the gasoline, water and oil required for an 8 to 10 hour operation, weighs only about 300 kilogrammes (661 pounds).

The various parts of the set are designed to be transported most easily. They make four packages, each of about 80 kilogrammes (176.4 pounds), and are fitted up or taken apart in about five minutes. The operative parts, motor, dynamo and accessories, are fitted on a frame, readily moved to and fro by means of handles. The small searchlight, which is handled independently of the motive part, comprises two conductors each 100 meters (328.1 feet) in length (wound on cable drums), and all adjusting arrangements, inclusive of the tripod frame, weigh only 47 kilogrammes (103.6 pounds).

It will readily be understood that an outfit of so moderate weight, designed to be loaded on four animals walking independently of one another, should be able easily to follow an army even on almost impracticable ground, e. g., in the highlands on the steepest and most narrow mountain paths. The searchlight will be used advantageously both in signaling backward and in keeping up a connection with detached posts. It will also be found most useful in watching the course of a river, or a chain of lakes, if the vegetation on the banks is too dense to allow any searchlight cars to approach. Another case where the new outfit is likely to render valuable services is that of the equipment of expeditionary forces and detached troops, likely to encounter extremely difficult ground. On incursions in colonies and other territory, the addition of portable searchlights will prove of inestimable service, in exploring and defending the ground, the more so as the outfit can at the same time be used for signaling.

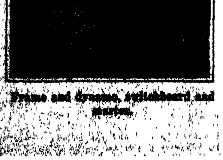
The portable outfit comprises a gasoline motor with radiator and fuel tank, a leather clutch and a dynamo, mounted on a common frame, a searchlight and tripod as above described, two cable drums, a water bag and the tool casing, the whole being readily carried by four mules in packages each of about 80 kilogrammes.



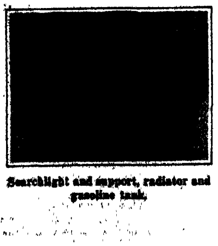
Complete outfit of the portable field searchlight.

The gasoline motor develops 4 to 6 horse-power at a speed of 1,500 revolutions per minute. It is equipped with a fly-wheel, magneto, governor and valve gear, cooled by an extra large thermosyphon radiator and fitted with a fan driven from the motor shaft. The oil tank and hand pump are fixed to the motor by means of a bracket. A leather clutch connects the motor with the shunt-wound dynamo, which at a speed of 1,500 revolutions per minute develops a tension of 65 volts and an intensity of 22 amperes. The inductor housing has been made of cast steel and the bearing brackets of aluminium, in order to keep down the weight. The most indispensable instruments and switches, an instantaneous switchout, a fuse, a voltmeter and two terminals for connecting up the two cables each 100 meters in length, have been provided. The motor, frame and radiator are fitted with handles allowing the whole set to be readily lifted.

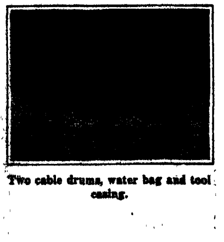
The four packages carried by the mules comprise the following parts: First mule: Searchlight and supports, radiator and water and cooled gasoline tank. Weight, 82 kilogrammes (180.8 pounds). Second mule: Frame, dynamo, and leather clutch, switchboard and instruments, inclusive of the starter Weight, 80 kilogrammes (176.4 pounds). Third mule: Gasoline motor and oil tank. Weight, 83 kilogrammes (183 pounds). Fourth mule: Two cable drums and 2 by 100 millimeters (0.08 by 3.94 inches) cable, filled water bag and tool casing. Weight 55 kilogrammes (121.1 pounds). The weight of the harness (saddle and accessories) varies between 27 and 30 kilogrammes (59.5 and 66.1 pounds).



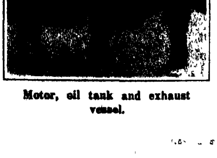
Frame and dynamo, switchboard and starter.



Searchlight and support, radiator and gasoline tank.



Two cable drums, water bag and tool casing.



Motor, oil tank and exhaust vessel.

The Expanding Weather Map

ON January 1st the Weather Bureau began publishing at its central office in Washington a daily telegraphic weather map of the northern hemisphere. It appears on the reverse side of the ordinary weather map of the United States (i. e., the lithographic map issued in Washington, which is larger and more complete than the maps issued in other cities throughout the country), and is drawn on a circum-polar projection. Although the observations plotted on this map are not strictly synchronous (e. g., observations taken in Japan at 4 oclock yesterday afternoon, Washington time, are brought into comparison with those taken in the eastern United States at 8 o'clock this morning), they coincide nearly enough in time to make plain the broad features of pressure and temperature distribution, and especially the vicissitudes of the great "centers of action" to which weather forecasters attach so much importance.

Aside from the compact network of reporting stations in the United States and Canada, the data on which the chart is based are rather sparse, the total number of other stations, including those in Alaska, being only forty-one; so that much of the map is obviously conjectural. This is a defect which will undoubtedly be remedied in time; probably through an agreement on the part of all civilized countries to exchange their weather reports by telegraph. The plan of a *réseau mondial* of this sort was a favorite idea of the late Teisserenc de Bort, and an international commission was formed some years ago to take steps toward its realization. The great blanks over the oceans, at present inevitable, will doubtless be partly filled up by wireless reports from marine observers, just as soon as the serious delays now involved in relaying messages from ship to ship have been eliminated or reduced to a minimum through improvements.

The United States Weather Bureau is to be congratulated not only upon being the first institution in the world to publish daily telegraphic weather maps of a hemisphere, but also upon setting the example of using on such maps dynamic units of barometric pressure (millibars) and degrees of temperature on the absolute scale. The isobars on the new maps are drawn for intervals of five millibars, and the isotherms for intervals of ten (in some places five) degrees absolute. Their appearance is neither strange nor confusing to persons habituated to the old units. The British Meteorological Office is planning to use these units on its regular daily weather map after May 1st of this year, and it seems certain that other countries will follow suit.

The advantages of the new units have already been set forth from time to time in the SCIENTIFIC AMERICAN.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Pertaining to Apparel.

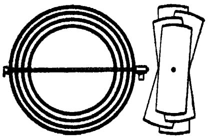
COLLAR SUPPORT.—L. M. GRAUBARTH, care of Josef Friedman, Inc., 114 Fifth Ave., New York, N. Y. The invention relates to negligee shirts having soft turned-down collars, and provides a support or stiffener arranged for convenient attachment to the collar to prevent the turned-down front portions of the collar from wrinkling up, and to hold the same in properly stretched positions, thus insuring at all times a neat appearance of the collar.

Electrical Devices.

ELECTRO-HYDRAULIC CONTROLLER.—C. ENGBERG, care of Engberg's Electric and Mechanical Works, St. Joseph, Mich. This invention comprises a system of valves particularly related with respect to means for controlling the valves, whereby the fluid may pass in different directions at will through the different chambers, a common outlet being provided.

ELECTRIC HAMMER.—J. O. FIELDS and R. L. FIELDS, 280 Downard St., Zanesville, Ohio. The principal object of the invention is to provide an improved contacting device especially adapted for use on electric hammers and adapted to be actuated by the beam of the said hammer whereby the distance through which the hammer head travels may be varied.

LOOSE COUPLED TUNING COIL.—A. C. GOWING and M. C. SPENCER, care of the former, 1 Lancaster Terrace, Worcester, Mass. This coil is for use in wireless telegraphy and other arts in the propagation of electric waves through space. It consists of primary and secondary windings, the former composing two sections which can be independently adjusted with regard to each other, and the latter likewise comprising two sections capable of independent adjustment, so that self-inductance of both windings can be regulated at will, and, at the same time, the mutual inductive effect of one winding upon the other can also be controlled with the utmost nicety

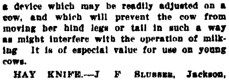


LOOSE COUPLED TUNING COIL.

Of Interest to Farmers.

RESTRAINING DEVICE.—J. R. INABNIT, Witsall, Mont. The object here is to provide a device which may be readily adjusted on a cow, and which will prevent the cow from moving her hind legs or tail in such a way as might interfere with the operation of milking. It is of especial value for use on young cows.

HAY KNIFE.—J. F. SLUSSER, Jackson, Idaho. This invention relates more particularly to a hay knife embodying a cutter which is movable with respect to the handle thereof, the purpose being to do away with the body strain incident to the usual form of hay cutting knife in cutting hay in the stack. The knife is easily operated without assuming cramped positions or working upon the knees.



HAY KNIFE.

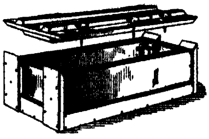
MEANS FOR IMPROVING LAND.—R. H. SPARKS, Terre Haute, Indiana. An object of the improvement is to provide a device by means of which sloping land that is being eroded from storm water, may be made to receive deposits of silt at certain places, and to maintain cultivation when said deposits are being made.

Of General Interest.

COLUMN.—J. F. MAY, 110 Conselyea St., Brooklyn, N. Y. This invention relates to columns of the type comprising a shell or casing of metal or other fireproof material designed to be filled with concrete, and the aim thereof is to produce an improved cap and base for the shell or casing forming the body of the column, so constructed that both the cap and the base will automatically center and lock themselves to the body of the column as soon as they are put in place.

MEANS FOR THE MAINTENANCE OF GAS IN CONFINEMENT.—S. E. BRETHERTON, 220 Mills Bldg., San Francisco, Cal. The invention relates to metallurgical and similar processes, and provides means for the maintenance of gas in confinement while agitating, decanting and refilling vessels with solutions either continuously or intermittently and without danger of free air from outside sources passing into the apparatus, thus preventing dilution of the gas and impairment of the decanting process.

ROUGH BOX.—W. M. GLOVERLEY, Ohiopyle, Pa. This invention relates to receptacles used for holding caskets and coffins, and used more particularly for shipping the latter, whether the coffins be empty or contain human remains, at burial. The lid is self adjusting in the sense that when fitted approximately into position it will move into exact registry, thus making a perfect fit. The screw holes are thus brought into precise registry, so as to facilitate the application of the screws. Moreover, the various bevel surfaces of the body portion promote ease of handling the casket in that the casket as lifted into and out of the body portion of the receptacle, is guided to some extent by the bevels.



ROUGH BOX.

STERILIZING AND PRESERVING APPARATUS.—N. J. DARDEN, Memphis, Tenn. This invention provides a device by means of which articles which are to be preserved may have the surrounding air removed and replaced by a fluid sterilizing medium, such as ozonated air, carbonic acid gas, etc., and in which the articles so treated may be sealed hermetically, so as to prevent the spoiling or decaying of the articles so treated. Mr. Darden has invented another sterilizing and preserving apparatus by means of which the sterilizing medium may be passed through the receptacle which contains the food-stuffs, first one way and then the other, thereby insuring the thorough permeation of the sterilizing medium.

FLUX FOR ALUMINIUM SOLDER.—H. HAMMAR, Delhi, N. Y. In the present invention the improvement has for its object the provision of a flux of aluminium solder consisting of soft soap and beeswax which may be easily manufactured and may be used with a blow pipe with the aluminium solder.

HEAD GATE.—J. T. FITCH, Helper, Utah. The object of this invention is to provide a simple, strong, inexpensive and balanced gate which can be quickly and easily operated and which is provided with means indicating the size of opening made by the gate.

METALLIC BUILDING.—W. W. TAYLOR, care of J. H. Taylor & Bro., 219 Glenridge Ave., Montclair, N. J. This invention relates to metallic buildings adapted to be shipped in knocked-down form, and more particularly to a building especially adapted for use as a garage. The various elements may be assembled with the parts properly adjusted and secured without the exercise of great skill, and without great care on the part of the workmen.

PROCESS FOR PRECIPITATION OF ZINC.—F. L. WILSON and S. E. BRETHERTON, care of latter, 220 Mills Bldg., San Francisco, Cal. The purpose in this invention is to obtain a constant precipitation of metallic zinc from an electrolytic bath and obviate the necessity of installing reduction furnaces for the production of the same.

STOPPER CAP.—R. H. MOLONEY, 315 73rd St., Brooklyn, N. Y. Among the principal objects which the present invention has in view are: to provide for bottle stoppers a detachable cap; and to provide a cap for the purpose set forth having a screw thread adapted to cut or sink into a cork of conventional construction.

BOOK MARKER.—W. A. OVERBECK, 822 E. Cleveland Ave., Salt Lake City, Utah. This invention relates more particularly to a member adapted to clamp a page. An object is to provide an inexpensive and simple book marker that will have a firm grip on the paper and will not injure or mar the page in places of contact with it.

GLASS CLEANER.—L. G. HATOSY, JR., 604 E. 135th St., New York, N. Y. This cleaner permits the barkeeper or other person to conveniently, quickly and thoroughly clean the glasses, and to allow of setting the cleaner into the washing or rinsing tank of a bar or of removing it therefrom whenever it is desired to do so for replacing worn out brushes by new ones or for other purposes.

HAME CLIP.—W. A. PICKARD, care of Mead & Whitcomb, 411 Sunset Bldg., Bellingham, Wash. This invention provides a clip so attached to the hame that weakening of the latter is avoided, and so connects the movable part of the clip to the stationary part carried by the hame that freedom of movement will be provided so that the trace will pull at right angles to its securing bolt, whereby strain against the animal's shoulders will be evenly distributed and splitting of material forming the trace, usually due to angular pull thereon, will be avoided.

Hardware and Tools.

COMMUTATOR SLOTTER.—J. E. [illegible], 708 Ninth Ave., Seattle, Wash. The improvement refers to a hand tool for slotting commutators, and it has for its general object the provision of a tool whereby the slots between the commutator bars of a dynamo-electric machine can be quickly and accurately made and with uniformly good results.

CIGAR TUCK CUTTER.—G. W. BOWMAN, 409 S. George St., York, Pa. This invention relates to cutters or trimmers for use by makers of cigars for trimming the ends or tucks thereof. It improves and simplifies the construction of the cigar cutters so as to be reliable and efficient in use, comparatively inexpensive to manufacture, and so designed as to insure a uniform size of cigar.

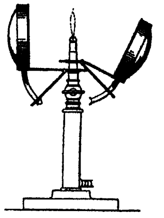
STRIPING TOOL.—J. E. [illegible], Harrington, Wash. This improvement has reference to striping tools for use by painters in wagon work and the like; and particularly to that class of tools in which the handle forms a container for the paint, and has means for detachably holding a striping brush.

WRENCH.—J. [illegible], [illegible] Emerson St., Lincoln, Neb. This invention relates to improvements in wrenches, and has for an object to provide an improved self-adjusting wrench which will automatically grip pipes, bolts, nuts and the like, without manipulation of any adjusting members.

LOCKING DEVICE FOR HAND DRILLS.—G. L. WILCOX, 167 W. 71st St., Manhattan, N. Y., N. Y. The purpose in this instance is to provide a new locking device for hand drills more especially designed to enable the user of the drill to readily and quickly manipulate the drill chuck for the insertion, fastening or removal of the boring or drilling tool.

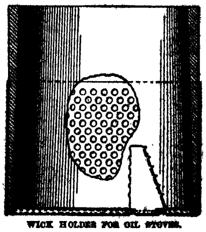
Heating and Lighting.

LIGHT INTENSIFIER.—G. [illegible], 23 John St., New York, N. Y. This invention relates to illumination or lighting apparatus, and has particular reference to easily and adjustably controlled means for increasing the light from a gas jet or any other suitable source of light for any purpose such, for instance, as for the use of workmen or artisans on a bench or the like. The lens meets the requirements of any particular user without interfering with or disturbing any other similar lens holders which may be located on the same jet.



LIGHT INTENSIFIER.

WICK HOLDER FOR OIL STOVES.—JOHN F. BITTLE, Lisbon, Iowa. The common form of a wick holder consists of a perforated cylindrical shell, the lower end of which is inturned and forms a binding over the wick, at the inside of the holder. As the wick in the old holder mentioned is permanently secured in place, it cannot be renewed, so that a new holder is required to renew the wick. In the present invention a novel clamping means is provided in connection with the holder, to detachably engage the wick, so that the remnant of a burned wick may be readily removed and a new wick secured to the holder.



WICK HOLDER FOR OIL STOVES.

HEATING SYSTEM.—P. [illegible], 54 Rue Lepic, Paris, France. This invention has for its object an arrangement for generating pressure and maintaining the same in steam generators without the use of fuel and the invention may be applied for instance to the so-called mixed electric plants, comprising electric machines combined with hydraulic and steam engines.

Household Utilities.

BATH SHOWER.—C. & C. [illegible], 304 W. 146th St., New York, N. Y. This bath shower occupies a small amount of space [illegible] the least amount of [illegible] into or [illegible] apparatus dispenses with [illegible] or apron to prevent [illegible] over the bathroom floor.

SADIRON STAND.—M. [illegible] K. Bartlett, [illegible] First National Bank Bldg., Oakland, Cal. This invention is a [illegible] stand or support for heated [illegible] called flatirons, and it is formed of a [illegible] produced by winding a strip of [illegible], and a metal band encircling the same and provided with a lateral handle, constructed integrally with the band. A series of rods extend through the body parallel to its surface and serve to reinforce the same so that it remains flat under all conditions of use.

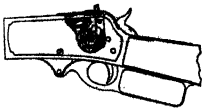
FASTENER FOR IRONING COVERS.—[illegible] M. BROOKMAN, 762 Spaulding St., [illegible], N. Y. This fastener is arranged to permit of conveniently and properly stretching the cover over the board and securely fastening the same in place on the board, and to permit of removing the cover from the board for removal and renewal of the facing sheets of the body of the cover.

WINDOW SHADE FIXTURE.—A. [illegible], 175 Clinton St., Brooklyn, N. Y., and L. [illegible], N. Y., N. Y. This invention provides retainers for the edges of window shades to normally hold the shade in desired positions; and provides means whereby if the shade is forced out of normal position, the same may be returned without further damage to the fabric thereof.

Machines and Mechanical Devices.

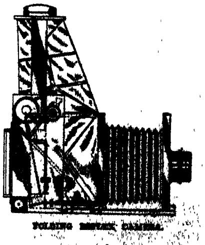
COMPOUND LEVER.—W. V. [illegible], London, England. Address Day, Davies & Hunt, 321 High Holborn, London, England. This invention has for its objects to construct a compound lever which will be compact and will enable the equivalent of an almost completely extended long limbed toggle to be utilized in the transmission of movement, so that an efficient and sustained leverage is available, and which may be adjusted to enable different operations to be obtained from a given actuation.

SIGHT FOR FIREARMS.—M. P. NASH, U. S. Navy, care of George C. Lawrence, 317 Washington Ave., Brooklyn, N. Y. This invention provides a sight for rifles and other firearms, and is arranged to permit the user of the firearm to conveniently and accurately raise or lower the eye-piece of the sight for different ranges to visually indicate the range to which the eye-piece is set, and to audibly indicate a change in setting the eye-piece. The engraving shows a side elevation with the sight fitted to a rifle. The inventor and his partner, Lieut. Commander J. M. Enochs, U. S. N., recently tested out the sight on the Government range at the Navy Yard, Mare Island, with very good results, it being fitted at the time with one of the new Springfield rifles.



SIGHT FOR FIREARMS.

CAMERA.—ANTHONY VORIS, 15 Cottage St., Jersey City, N. J. This invention relates to photographic apparatus, particularly to devices known as folding reflex cameras. It permits the operator to view a full size non-inverted image up to the moment of exposure. The apparatus of which a side view of a slightly modified form is shown in the engraving, may be folded into a very compact casing or housing when not in use. Means provide for automatically and quickly erecting the focusing hood and mirror upon dropping the [illegible] and vice versa. Provision is made for the use of a pleated bellows when long [illegible] are used, and their removal for [illegible]. This apparatus has in addition many other novel features of construction and operation.



FOLDING REFLEX CAMERA.

COMBINATION LOCK.—[illegible], Jenkins, Ky. This invention [illegible] wherein [illegible] between [illegible]

[illegible]

[illegible] MACHINE.—C. C. [illegible], care of [illegible] Co., 38 Wall St., N. Y., N. Y. [illegible] is an improved [illegible] and its object is to devise a [illegible] by means of which a number of sheets of paper or cardboard can be divided into a number of small pieces of regular shape, with little or no waste of the material employed.

HEAD GATE.—J. E. [illegible], care of Milwaukee House, Deer Lodge, Mont., and W. D. [illegible], Aberdeen, Idaho. The improvement is capable of embodiment either in a permanent head gate, or in a portable head gate adapted to be located at any point in a ditch, to raise water therein where desired. Valve means are provided for commanding the opening in the gate, and a novel arrangement of manually-controlled operating rod and guide therefor.

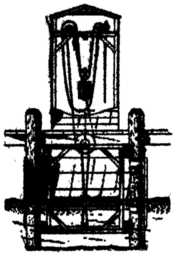
SAFETY DEVICE WITH COMBINATIONS FOR LOCKS OF ALL KINDS.—L. J. M. Dassand, 39 Rue de Lyon, Paris, France. The results accomplished by this device are due not only to the movableness of the safety elements or members located in the lock, but also to a key having removable members or counterparts in order that the change of the safety elements or members effected in the lock can also be effected instantaneously on the key, to allow of obtaining the necessary cooperation between these two parts of the lock.

WASHING OUT AND REFINING MACHINE.—H. Paats, 2 Vogelgesang, Burg, near Magdeburg, Germany. This invention relates to starch making machinery, and its object is to provide a washing out and refining machine arranged to effectively separate the starch from the pulp, and to allow of carrying on the washing out and refining operations in a single machine.

MITERING MACHINE.—F. Maximilian, 521 W. 37th St., New York, N. Y. This machine is more particularly adapted for glass-working. The principal object is to provide a machine especially adapted to miter glass through the aid of suitable tools, the construction and arrangement being such that the feeding means for the said tools is avoided.

Prime Movers and Their Accessories.

TIDE MOTOR.—W. Braunsdorf, 3440 Broadway, N. Y., N. Y. This invention relates to tide motors and particularly to power devices of this character adapted to operate substantially automatically in accordance with rise and fall of the tide. A float and means are provided to control the vertical reciprocations thereof with the tide and to cause the float to automatically grip an endless chain to cause the same to be operated from the float while the latter is rising or falling. The power storage device when detached from the tide motor can be applied to store power on windmills, and can be used as a hand weight motor for home use. The inventor claims that the power produced by his tide motor will cost one third of the price of electric power.



TIDE MOTOR.

VALVE FOR INTERNAL COMBUSTION ENGINES.—O. Ernst, Larchmont, N. Y. The valve is preferably of the rotary type, and the inventor's object is to provide a construction of this sort in which all defects inherent in rotary valves for gasoline motors are eliminated. To this end he constructs a valve with members that are so mounted as to have a certain degree of [illegible] play in the bearings [illegible] of the same.

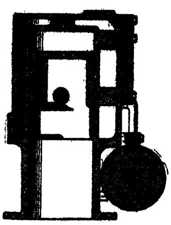
VALVE FOR INTERNAL COMBUSTION ENGINES.

[illegible]

object here is to provide a form of packing which will be associated with a valve in such a way as to make the same fit snugly at all times to its seat and totally eliminate leakage of steam or other fluid between said valve and the sides of the casing in which the same is contained.

GASOLINE FILTER.—C. A. Post. Address Fred Catchpole, Pagosa Springs, Colo. This simple device is adapted to be interposed between the source of supply and the carbureter for thoroughly and automatically purifying the liquid fuel, and wherein means is provided for shutting off the supply of fuel when the filter needs cleaning.

GAS ENGINE VALVE.—F. C. Gonzales, care of Ripley Congregational Church, Traer, Iowa. This invention is an improvement in gas engine valves, and has for its object, the provision of a direct acting valve for use with engines of the character specified, which will be comparatively noiseless in operation, simple in construction and in operation, accessible for the cleaning or the like, and having a large bearing surface, so that wear is reduced to a minimum.



GAS ENGINE VALVE.

PISTON RING.—H. H. Patrick, 50 Sandwell road, Handsworth, Birmingham, England. This invention relates to piston rings, for, more especially, internal combustion engines, although it is not limited to such rings, being applicable to cast iron and steel piston rings for a variety of purposes. In this invention the method of making split piston rings consists in the employment of a pair of similar and coaxial metal rings and uniting a pair of opposite overlapping ends along a portion of their adjacent side faces by welding.

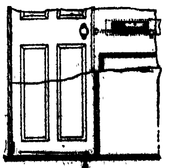
EXPLOSION MOTOR.—James MacConaghy, deceased, Boulogne-Sur-Mer, France, care of Charles Philips, 1122 Mission St., San Francisco, Cal. In the present patent the invention has for its object an explosion motor of the multiple cylinder type, capable of developing a great horse-power under a small volume and applicable by this fact, either to motor vehicles, or to apparatus for aerial locomotion.

Railways and Their Accessories.

CAR COUPLING.—C. A. McKeeahan, 420 Air Brake Ave., Wilmerding, Pa. This coupler is provided with a block for locking a tail piece of the knuckle, there being a lever, one arm of which is adapted to be engaged by the block, the block on the other arm of the lever engaging the cam surfaces of the tail piece to operate the knuckle as the block is raised or lowered. Means provide for raising or lowering the block from the side of the car.

SMOKE CONSUMER.—J. O. Richard, 515 Michigan Ave., Hammond, Indiana. The principal object here is to provide a smoke consumer especially adapted for use on locomotives, whereby the boiler pressure is utilized to provide a draft in order to carry back the products of combustion into the fire box after such products have been mixed with a desirable quantity of air.

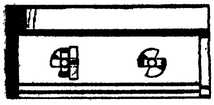
FARE REGISTER.—L. J. Harris, Albany, Ga. This invention comprehends mechanism controlled partly by the weight of the passenger entering the car, and partly by a voluntary or manual act of the passenger independently of his weight, for preparing a record of the number of passengers taken aboard at various stations, and also for indicating respectively the various destinations for which the several passengers are bound.



FARE REGISTER.

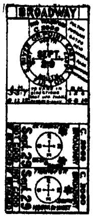
MEANS FOR SUPPORTING AND RELEASING RETAINING STAKES.—J. D. Mauch and F. Martin, Rib Lake, Wis. This invention provides a casing having means whereby it can be secured to the bolster of a car, which is provided with a bolt having locking means. A shoe which carries the stake has means adapted to engage the casing and to be secured by the bolt to the casing, with the locking means preventing the accidental displacement of the shoe from the casing.

BOLT.—J. S. Wait, Jr., and A. Halliday, care of the former, 324 Third Ave., Two Harbors, Minn. This invention is an improvement in bolts, and has for its object the provision of a bolt for use with fish plates for connecting rail ends so constructed that the fish plates may be clamped together on the rail ends, and held firmly in such position, without the necessity of threaded holding nuts and bolts.



BOLT FOR USE WITH FISH PLATES.

TRANSFER TICKET.—W. Klein, Jr., 11 Devoe St., Brooklyn, N. Y. This ticket is particularly designed and adapted for use in transferring passengers from one line of cars to intersecting lines, and for this purpose the ticket is composed of a body or main portion, transfer and retransfer portions having various peculiarities. The accompanying engraving represents the transfer, which is a composite ticket.



TRANSFER TICKET.

RAIL JOINT.—J. W. Enright, 862 Tchoupitoulas St., New Orleans, La. This invention relates to railway construction and has particular reference to means for connecting the adjacent ends of the railway rails. Among the objects is the provision of a rail joint which may be rolled and which, when in assembled position, serves to clamp the rails in a peculiar vise-like manner.

MEANS FOR THE INTERCHANGE OF MESSAGES BETWEEN A STATION AND A MOVING CAR.—O. H. Smith and J. L. Smith, Stratford, Pennsylvania. Address the former. This invention relates to mechanism of the character set forth in a previous patent, No. 1,042,983, issued to these inventors. It provides a system of tubing leading from a railway station or other building in the proximity to a railway track, such tubing being adapted to deliver carriers to and from a car, such carriers being received and deposited by the car as it moves along.

Pertaining to Recreation.

HAND BALL GLOVE.—J. I. Brokaw, 160 W. 66th St., Manhattan, N. Y., N. Y. The purpose in this case is to provide a glove with which it is possible for a player to return the ball accurately, and with great speed. In the game of hand ball, gloves are worn not as a protection for the hand, but to increase the efficiency of the player.

Vehicles and Their Accessories.

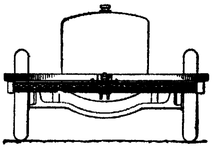
TIRE DEFLATING CAP.—J. H. Hard, Allen, Neb. A cut of the device appeared in this journal November 22nd, 1913. It consists of two caps joined at their bases; either cap screwing upon a valve stem; one serving as a valve cap, the other having a central pin depressing the valve, releasing air through holes in the wall of the cap. Also a core remover with a base which screws into either cap, where it may be carried when not in use.

SPRING WHEEL.—C. N. Snowden, Soledad, Guantanamo, Cuba. This invention pertains to spring wheels more particularly designed for use on automobiles, and more especially to that class in which there is an inner hub and spoke section having a rim, and an outer tire rim. The invention provides a novel spring means affording a cushioned connection between the inner rim and the tire rim.

VARIABLE SPEED MECHANISM.—D. E. Crouse and C. G. Eidson, Annapolis, Md. This invention provides a mechanism for use in automobiles and similar vehicles which will dispense with the noise ordinarily occasioned when gears are brought into mesh. The invention provides a variable speed mechanism in which the changing of the speed is accomplished by the mere shifting of a switch in an electric circuit.

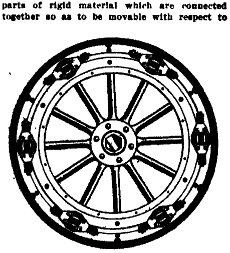
AUTOMOBILE LAMP.—W. F. Dorsman, Box 96, Cumberland, Md. The present invention relates to automobile lamps, and particularly to that character of lamps and their attachments by which the lamps are caused to turn on vertical pivots for the purpose of following the direction of turning movement of the machine, connections between the lamps and steering gear being had for this purpose.

VEHICLE FENDER.—D. Ghezzi, care of C. Zerbani, 846 Broadway, N. Y., N. Y. Among the principal objects which the present invention has in view are: to provide an apparatus of the character named having a yielding buffer and grasping arms arranged to support a body from falling; and to provide means whereon the body may rest, or recline after being lifted from the ground. A buffer may be placed sufficiently low to catch and carry a child while arms may be disposed so that if the buffer be struck, they will grasp a person at the height of the hips, waist or shoulder.



VEHICLE FENDER.

RESILIENT TIRE.—R. Curry, 1436 Prospect Ave., Bronx, N. Y., N. Y. The intention here is to do away with the necessity of using rubber tires, by providing a tire made up of parts of rigid material which are connected together so as to be movable with respect to one another, and so constructed that the same can be applied to almost any wheel now in use. The extent to which the principal parts are movable is regulated by cushioning devices or suitable resilient means which are introduced between the same, and the whole is suitably incased to guard against the intrusion of mud or dirt when the same is in service.



RESILIENT TIRE.

NON-SKID TIRE SHOE.—H. Strongson, 68 E. 97th St., Manhattan, N. Y., N. Y. This invention provides an article having spaced-apart members moving relative to the tire to form independent gripping sections to permit movement of the tire thereon, provides resilient means for returning the gripping sections to normal position, provides for adjusting the shoe to wheels and tires of different dimensions; constructs an article to permit the removal for repair or replacement of sections thereof; and provides an article which may be folded or packed within small compass.

Designs.

DESIGN FOR A DOLL HEAD.—J. G. Kaempfer, care of Maurice L. Shaine, 850 Broadway, N. Y., N. Y. In this ornamental design for a doll head, the head is round, the face chubby, the eyes very large and the mouth open. The hair is smooth except a slight wave and a lock curling down the forehead.

Note.—Copies of any of these patents will be furnished by the Scientific American for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

Safety in Steel Works

(Concluded from page 122.)

which was provided, at heavy expense, in a pipe mill of the National Tube Company at McKeesport, Pa. When the building was erected no provision was made for the cleaning of the windows in the saw-tooth roof. The window cleaner had to cling to the molding and the steel work of the roof while cleaning the inwardly slanting windows, and accidents were not infrequent. Accordingly, tracks were laid along the windows and a trolley provided to run the entire length of the building. As the wheels of the trolley have ball-bearings, one man can easily move the vehicle along as he cleans the windows.

No machinery is now bought by the Steel Corporation without provisions for safeguarding all possible points of danger. In the two pictures of a bevel gear, which we illustrate, one shows the gears completely covered and all the oiling lids closed, while in the other the guards have been removed to show the gears, which were at one time uncovered and constant menaces to the lives and limbs of the workmen. The company's draughtsmen in designing new machines or making repairs for old machines have the safety idea constantly before them. They are required to make sure that all gears are covered, that all couplings are recessed, etc., and that every possible source of danger is guarded against. Every blueprint must be checked by a safety inspector in order to make sure that it comes within the regulations.

A common source of danger may be found in the ordinary planer with its open bed between the ways. The machinist who operates this planer is quite apt to use this space for storage purposes, and he is liable to have his hand caught by the table as he reaches down into the bed for something. We have heard of an accident in which a man stuck his head down into the bed in search of something, and the returning table promptly decapitated him. Accordingly the ruling has now gone forth, that the planer beds must be covered with sheet iron. Even the oil wells in a planer's ways must be covered. In one of our photographs may be seen the "skull cracker" with which large castings are broken up. The skull cracker is an enormous ball of iron which is lifted by an electromagnet. On demagnetizing the electromagnet the ball drops, striking the casting with a powerful blow. Flying fragments make this operation dangerous The customary barrier of boiler iron riveted to a steel frame has been found inadequate; for sometimes the fragments are thrown with force enough to cut clear through the barrier and injure people outside. This led to the erection of another barrier within the boiler iron wall, consisting of a series of iron tubes supported upright in a concrete base and filled with concrete, so as to form a stout stockade The force with which the fragments sometimes strike this stockade will be noted in the accompanying illustration by the dents made in the pipes. One of the pipes near the right-hand side of the picture will be seen to be cracked Unfortunately lack of space prevents us from illustrating the thousands of different safety devices, many of them exceedingly interesting, that have been developed in steel plants.

The organized safety movement of the United States Steel Corporation dates from 1906. In 1907 the rate of accidents was reduced to such an extent that 532 men were saved from serious injury. By the end of 1912, 8,801 persons had been saved. Surely this record shows that the work is worth while even if all humanitarian considerations be ignored.

The American Museum of Safety

(Concluded from page 114.)

by suction. The most striking part of the Pulmotor is a small leather accordion bellows, which effects the automatic reversal of the apparatus from suction to delivery, and *vice versa*, when essential. The bellows is connected with the air tubes. During inflation, the same pressure obtains in the bellows as in the lungs, and as soon as the latter are filled, the bellows becomes inflated, and in moving forward, causes the valve to be automatically reversed into position for suction. The operation is now reversed, and as soon as the lungs have been emptied, the bellows contracts and automatically reverses the valve again into position for inflating—and so on.

The medal was awarded for the fifth time last December to the Welin Marine Equipment Company for a chain of safety devices, including the Welin davit and the Lundin lifeboat. These devices have been fully described in the SCIENTIFIC AMERICAN for December 20th, 1913. Lifeboats are like a fire escape, they are wanted desperately when they are wanted at all, so that the boats themselves must be safely launched and kept afloat until succor arrives. The boats described in that issue fulfill admirably all the requirements of safe operation.

Such in brief is the history of the SCIENTIFIC AMERICAN Medal. The high class of the devices honored speaks well for the professional ability of the juries, the members of which have included some of the most eminent engineers in the country.

Proposed Improvement of the Patent Office

FOR many years the storage of the important records of the Patent Office as well as of the many copies of patents which have accumulated beyond all anticipation, has caused much concern. Many of the halls of the Patent Office are crowded with the accumulation.

It is now proposed to excavate the open court of the Patent Office to a sufficient depth below the present surface to provide a two-story storage place of about 15 feet, giving a headway of 7½ feet in each story.

The roof of the structure, so provided, is to be covered with soil and grass as at present with the walks covered with vault glass to admit sufficient light.

The intermediate floor of the storage place will be of metal grating so that light and air may circulate freely between the floors, and the Ninth Street end of the structure is to be made fireproof for the storage of the valuable records of the Office.

By leaving a space of seven or eight feet all round the court structure, sufficient ventilation may be secured and the structure adapted for the storage of patent copies and other records, but it is not contemplated that any part of the structure shall be utilized for work rooms.

The appropriation of $220,000 to erect a building has already been granted, and it is now proposed to ask Congress to permit the use of this appropriation for the building of the vault space.

By the proposed arrangement all patent copies can be stored at one place, avoiding the distribution thereof throughout practically the entire Patent Office building as at present. This will facilitate not only the business of the Patent Office in securing the copies for its own use, but also facilitate the delivery of copies to attorneys and others in the transaction of business, while a perfectly fireproof compartment for the valuable records of the Office, at present exposed to fire risk, will be provided.

The Eruption of Sakurajima

ON January 12th the volcano Sakurajima, in southern Japan, burst into violent eruption. This volcano, which according to Naumann, was formed in the year 718 A. D., occupies the middle of the island of Sakura, opposite and a few miles distant from the large city of Kagoshima (the center of the Satsuma rebellion and of many other important events in the history of Japan). Both Kagoshima and the neighboring volcano are favorite resorts of occidental travelers. Sakurajima has had seven previous eruptions, all of them explosive, the latest in 1860. A much more violent one occurred in 1779; this produced such an impression that it has been commemorated locally ever since by a monthly festival.

HARRY P. STIMSON

[illegible] by the eruption [illegible] across the channel. About half of the 3,500 houses in the island were destroyed.

The eruption was accompanied by frequent shocks of earthquake, which, though not of extreme severity, did some damage in Kagoshima, and the city was also invaded by waves from the bay. Most of the inhabitants of Kagoshima closed their houses and fled. About twenty casualties occurred here.

After partially subsiding a renewal of volcanic activity occurred on the night of the 16th. Simultaneously with the eruptions of Sakurajima the volcano of Kirishimayama, lying about 30 miles farther north, was in eruption, and violent rumblings were heard from Aso-san, the largest volcanic crater in the world, belonging to the same group.

Prof. F. Omori, Japan's leading vulcanologist and seismologist, is quoted in press dispatches as having expressed the opinion that the whole volcanic range of Kiusiu has entered upon one of its recurrent periods of activity, and that other eruptions are imminent.

Dried Fruits and Their Use

IN the yearbook of the Department of Agriculture for 1912, there appears an article prepared by C. F. Langworthy on raisins, figs, and other dried fruits and their use.

To determine which of two fruits is really the more economical, says Mr. Langworthy, one should know not only the cost of each per pound, but also the amount of protein and energy a pound would supply, and should take into account the amount of material, fuel, and labor required to prepare the two foods for the table. Grapes commonly cost less per pound than raisins, but a given sum spent for fresh fruit will buy a smaller amount of nutritive material, since the proportion of water is much higher than in the raisins. On the other hand, one can think of circumstances under which low-priced fresh fruit, which may be eaten as purchased, would in the end be as economical as a somewhat cheaper dried fruit, since the latter would require sugar and fuel and time to make it ready for the table. Such considerations as the ease of obtaining a supply, convenience of use, the liking for a particular product, and many other things besides cost must also be taken into account in comparing dried with fresh fruits. Attention should also be directed to the question of refuse, or inedible material. If seeded and unseeded raisins cost the same price per pound, the former would be more economical as well as more convenient, since the purchaser would not have to pay for the seeds.

As a whole, dried fruits can be called reasonable in price as compared with other common articles of diet. This has been shown by numerous studies made in connection with the nutrition investigations of the Office of Experiment Stations. Some less general comparisons may also be made from the results of such studies. For instance, it appears that practically all the fruit products contain little protein, and as sources of this food constituent are so much more expensive than the cereals and dried legumes and most animal foods that there is practically no comparison between them. However, as sources of energy, derived almost entirely from their sugars and other carbohydrates, dried fruits are decidedly cheaper than meats, and compare favorably with dairy products, but are more expensive than cereals and starchy vegetables, such as dried beans and potatoes. When compared with one another, the differences in composition are relatively small, so that the selling price of different sorts of dried fruits is the main point when one is considering relative economy. This means that the housewife who wishes to economize can secure as much nutritive material from dried apples at a low price per pound as she can from a fancy grade of dried [illegible] at a much higher price per pound, though the flavor may not please her so well.

When every penny spent for food must bring the largest returns in actual nutritive value, questions of flavor and attractive appearance are of secondary importance, but when the income allows a range of choice, it is perfectly justifiable to consider them, and a family which can afford expensive meats and selected grapefruit can also purchase fine layer raisins for use as dessert, and fancy brands of other dried fruits. In the family where means are limited, the cheaper sorts must be chosen, but under any circumstances fresh and dried fruits should not be thought of as a luxury, since they may be used as an integral part of the diet to supply needed nutritive material, as well as add to the attractiveness and palatability of the daily fare. If they are to be eaten raw, care should always be taken to select brands which are made and marketed in a cleanly way, and most persons would prefer to pay a few cents more per pound, if necessary, to be certain that the brands are of this character. Dried fruits in sealed cartons or packages are much less readily soiled in market than those sold from open boxes. Unfortunately, neither price nor appearance is necessarily an index to cleanliness, and it is often difficult for the ordinary buyer to know where and how dried fruit was prepared and marketed. Those who are familiar with the facts in the case believe that the use of evaporators and other mechanical devices results in a much cleaner product than the old-fashioned methods, and that American dried fruits are the equal of any in this respect, and much more cleanly than those which are imported from Mediterranean regions. In using dried fruits in cookery every attempt should be made to secure clean, wholesome goods, to remove any bits of stem or other material accidentally present, and to wash the fruits before using them if they are not already clean. The heat of cooking will sterilize them, to be sure, but most of us prefer material which we do not need to sterilize to render it safe and wholesome.

Whether used by themselves as substitutes for fresh or preserved fruits, or mixed into cakes, puddings, confectionery, and other dishes, dried fruits offer a wholesome, nutritious, and economical way of securing variety in the diet, and are especially useful where the supply of fresh fruits is limited, or where storage space for fresh fruits is lacking.

Variations in Atmospheric Ozone

By Harry N. Holmes

THE existence of ozone in the atmosphere has often been disputed and the tests obtained ascribed to hydrogen peroxide, nitrogen peroxide and other compounds occasionally found in the air. Recent experiments, however, prove that variable amounts of ozone do exist in the lower air, though probably not more than one part in seven hundred thousand. The most conclusive test known is that with the so-called "tetramethyl base" paper. To be exact it is really tetramethyldiamidodiphenylmethane. A very small amount of this powder is dissolved in water containing a little acetic acid and strips of white filter paper are partly immersed in the solution. Ozone turns the exposed portions of the paper violet, while nitrogen peroxide turns it yellow, and hydrogen peroxide has no effect.

Various theories are advanced to account for the presence of ozone in the atmosphere. The electric discharge during thunderstorms is a favorite cause, though such an explanation is hardly in accord with the fact that in winter when there is very little thunder and lightning the air is richest in ozone. Besanez ascribes its formation to the rapid evaporation of water, yet other scientists insist that rapid evaporation of water in the sunlight produces hydrogen peroxide, thus accounting for the beneficial effects of sea air.

The most probable causes, however, are found in the silent electric discharge such as the aurora borealis and the action of ultra-violet rays of sunlight on cold, dry oxygen. Ladenburg and Lehman have

ELECTRENE

FIRE EXTINGUISHERS

deserve your consideration. Prominent individuals in every walk of life have considered **Electrene** Fire Extinguishers—and have bought.

The President of the United States has **Electrene Fire Extinguishers** on his motor cars.

Large corporations of all sorts have considered **Electrene Extinguishers**—and have bought—and bought again.

The constant stream of repeat orders is the surest proof that these modern and new-principled Extinguishers are in demand.

The fact that we are ready to enter into open test and competition with any Extinguisher of a similar type is the surest proof that **Electrene** has points and features not possessed by any other.

For instance, the mere fact that you don't have to pump, has a two-fold advantage—it takes no energy and because of this your "aim" is sure.

The **Electrene** Fire Extinguisher is standard in the New York Fire Department.

In one (name on request) large town every fire (for the last six months) has been extinguished by the Fire Department solely with **Electrene** — avoiding all water damage.

Among the Big Users are:

The Brooklyn Rapid Transit Company which has placed 1,000 ELECTRENE Fire Extinguishers on its Electric Cars.

The new Biltmore and the Waldorf-Astoria with 300 ELECTRENE Fire Extinguishers in their equipment.

The New York Central which has equipped its electric locomotives with ELECTRENE Fire Extinguishers.

The Gold Medal and Diploma of Merit at the International Exhibition of Safety and Sanitation

held in the Grand Central Palace, New York, December 11th to 20th, is a clinching proof of its excellence — if further proof is necessary.

Will you give the **Electrene Fire Extinguisher** enough consideration to send for our illustrated booklet describing it in detail—what it is—what it will do—and what it actually has done.

ELECTRENE COMPANY
Whitehall Building New York

shown that ozone has a number of absorption bands scattered over a wide range of the spectrum, and by a study of these bands Angström detected the presence of a large amount of atmospheric ozone. Naturally since little of it is found in the lower air it must lie in the upper air.

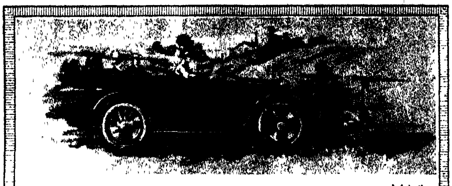
Humphreys demonstrated that a blanket of ozone around the earth would be much less permeable to earth radiations than to solar rays and must therefore act as a temperature regulator. Ultra-violet rays of sunlight undoubtedly convert oxygen into ozone, but, unfortunately for us, these rays are absorbed by air so that only a small fraction reaches the lower air. In the upper strata this ozonizing action is great, thus accounting for the presence of considerable amounts of ozone several miles above the earth.

It is evident that any decrease in the sun's radiation must be followed by a decrease in the formation of this ozone blanket, thus permitting more of the earth's heat to escape. Humphreys observed that sun spot maxima were always accompanied by a decrease in terrestrial temperatures many times that which could be accounted for by the decrease in radiation from the spot areas alone. A compensating effect in high latitudes is the action of sun spot maxima in increasing auroral displays, which in turn form increasing amounts of ozone. In equatorial regions there is no such compensation, so the upper air in the torrid zone must have a greater diathermacy to earth radiations. This results in the comparatively low temperature and great elevation of the equatorial isothermal air. This hypothesis is sustained by the facts, for the isothermal air in the tropics is two miles higher and 27 deg. Fahr. colder than in middle latitudes.

The theory and evidence given above receive further support from the weather observations of the author, carried on for a period of nearly two years. Only approximate measurements of the variations in the ozone content of the atmosphere were made, but this record is of considerable value. One of the most striking observations made was that thunderstorms—always supposed to form what little ozone the lower air contained—were really of minor importance in this connection. Any clear, snappy winter day will yield better ozone tests than the liveliest kind of a summer thunderstorm. Furthermore, since heat and moisture are unfavorable to the existence of ozone, the amount developed by summer lightning is quickly destroyed. Not so in winter, when the conditions for the preservation of ozone are frequently ideal—low temperatures and absence of dust after snows.

The whole series of tests studied in connection with the daily government weather maps proved beyond a doubt that the maximum ozone content of pure country air was found only when "high" barometric areas were so near that the air from great heights rapidly flowed down to the observer. Owing to greater extremes of temperature the storm areas are more frequent and intense in winter; hence the quicker transfer of high air to the surface. It is, of course, understood that "high" pressure areas are merely heaped up masses of air moving across the continent as regions of fair weather. The top of this heap falls and flows out in all directions from the center. The nearer the observer is to this center the greater the amount of ozone he finds in the air. If so far away that he is actually in a "low" area the winds blowing to him from the "high" will have traveled over a long stretch of the earth's surface, and the ozone beginning the journey will have been destroyed by moisture, dust, organic matter and, in some seasons, by heat.

These observations confirm the hypothesis that nearly all the ozone found in the lower air was made miles above the earth by the action of ultra-violet light on cold, dry oxygen. Naturally the quicker great bodies of this ozonized air fall to the earth the less chance there is for destruction of the ozone. Strong "high" barometric areas furnish these conditions. Such areas always produce cooler weather, and it may be objected that the



YOU can forget heavy or rough going when you ride on Detroit Springs. They are provedly *Flexible, Sturdy, Safe.*

The roughest stretch of road your car has power to get over is scarcely a real trial compared to the tests Detroit Springs must undergo in our factory.

You need not fear a break—or even a minor change in their flexibility. Every road blow and vibration that a spring could possibly meet in years is condensed into our three decisive ordeals—the "Initial Test," the "Hardness Test," the "Capacity Test."

Look for the trade mark—it is your insurance of comfort, safety, of a longer life for your tires and your car.

JUST PUBLISHED 1914 EDITION

THE MODERN
GAS TRACTOR

By VICTOR W. PAGÉ, M. E.

Author of "The Modern Gasoline Automobile," Etc., Etc.

A COMPLETE TREATISE DESCRIBING ALL TYPES AND SIZES OF GASOLINE, KEROSENE AND OIL TRACTORS. CONSIDERS DESIGN AND CONSTRUCTION EXHAUSTIVELY; GIVES COMPLETE INSTRUCTIONS FOR CARE, OPERATION AND REPAIR; OUTLINES ALL PRACTICAL APPLICATIONS ON THE ROAD AND IN THE FIELD. THE BEST AND LATEST WORK ON FARM TRACTORS AND TRACTOR POWER PLANTS.

5¼x7½ Inches. Cloth. 475 Pages. 204 Illustrations. 3 Folding Plates.

PRICE $2.00

A modern exposition in the language of the field showing and describing every recent improvement in tractors and auxiliary appliances. All money-making farms use power. Learn how to apply it now.

This work is written by a recognized authority on self-propelled vehicles and internal combustion motors. Everything is explained so simply that anyone of average intelligence may obtain a comprehensive knowledge of gas tractor operation, maintenance and repair. Tells how they are constructed and explains fully the reasons for varying designs. Contains special chapters on driving the tractor on field and road, what to expect from tractors in various kinds of work, cost of operation and money-making hints on repairs. It describes all ignition systems, all types of gasoline and kerosene vaporizers and carburetors, latest forms of power plants and installation, clutches, speed changing and reversing gears and all frame parts and their functions. Tells how to tell brake horsepower from draw bar or horse equivalent power, how to make adjustments to power plants, change speed gearing and other parts. Describes tools for tractor repair and gives plans for tractor sheds so they can be used in winter for stationary power or workshops where all repairs may be made. Outlines control systems of leading types and shows simple hitches for working various implements in combination. Describes fully tractors for small farms and orchards as well as types of the largest capacity. All illustrations are plainly marked with all important parts indicated so they may be easily identified. Drawings are simple but in correct proportion. Every illustration has been specially made for this book.

ALL FARMERS, STUDENTS, BLACKSMITHS, MECHANICS, SALESMEN, IMPLEMENT DEALERS, DESIGNERS AND ENGINEERS NEED THIS WORK

Written in language understood by all. No technical terms.

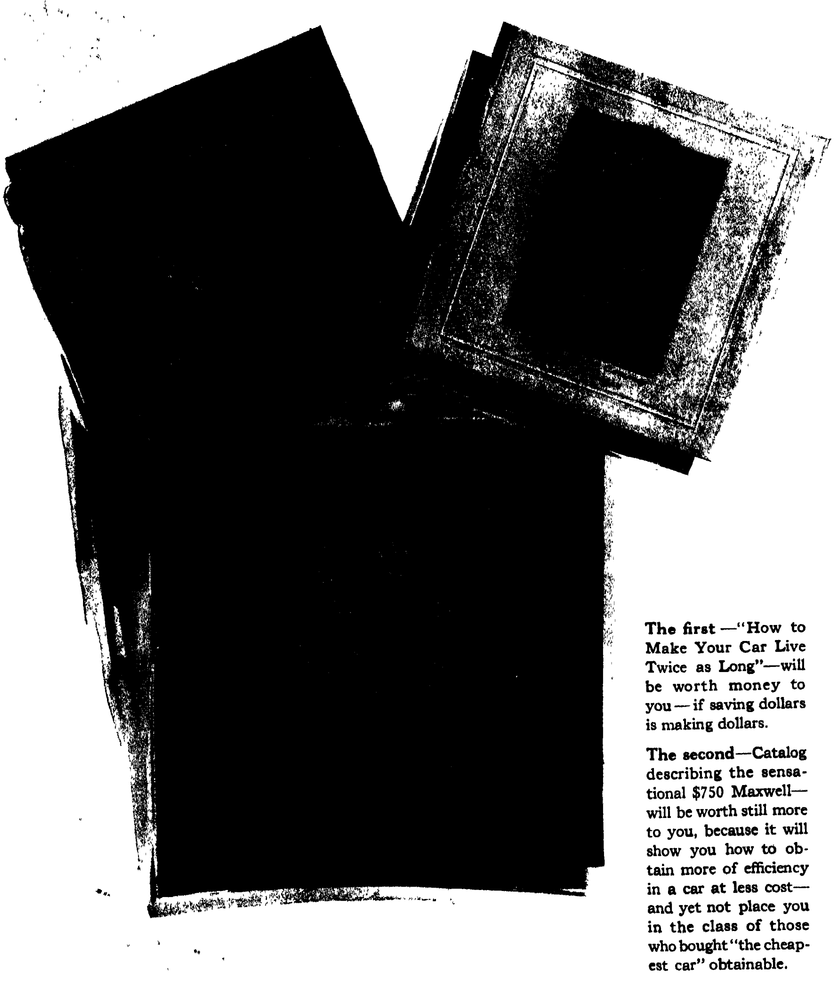
King's House, Kingsway, London, England

We'll be glad to send you these three beautiful books



The first—"How to Make Your Car Live Twice as Long"—will be worth money to you—if saving dollars is making dollars.

The second—Catalog describing the sensational $750 Maxwell—will be worth still more to you, because it will show you how to obtain more of efficiency in a car at less cost—and yet not place you in the class of those who bought "the cheapest car" obtainable.

And the third—"Maxwell Factories and Facilities"—will tell you more about automobile making than perhaps you've ever known. Incidentally, the 175 views of operations in Maxwell plants will illustrate to you that we put the highest quality in Maxwell cars—and how we do it.

preservative influence of low temperatures will alone account for the phenomena recorded. Such is not the case, for the coldest weather did not always produce the best ozone tests. On January 29th, 1912, Indiana (where the observations were made) was in a "low" pressure area and practically no ozone tests could be secured. The next day, January 30th, a powerful "high" area advanced from the Rockies and covered Indiana. The best tests of the year were obtained, although the temperature was only 21 deg. Fahr. *above* zero. On another day when the temperature was 30 deg. Fahr. *below* zero a very good test was secured, but still much inferior to that of January 30th.

Obviously the time to get out of doors is when the barometer is rising rapidly, even if the cold is intense. The treatment of tuberculosis patients in the Adirondacks hospitals, where they are pushed out of doors in the most severe winter weather, is justified. Such apparently cruel weather is caused by a rapid succession of "high" areas, and the accompanying ozone stimulates the nerves governing respiration and circulation.

The hot summer of 1911 was poor ozone weather. January and February of 1912 were remarkably fine (and it was an unusually healthy winter), the summer of 1912 much above the average summer weather, but this present winter has been rather poor in ozone—certainly much inferior to the previous winter. "What is so rare as a day in June?" might well have been asked of June, 1912, a month that, in the Middle West, brought more ozone than some winter months. June, 1911, deserved no poetic raptures, for it furnished very ordinary ozone weather.

A New Fish-curing Method

A METHOD has recently been introduced in Halifax, Nova Scotia, which promises to revolutionize the fish industry wherever carried on to any considerable extent, says Vice Consul General Eugene M. Lamb.

This process is based upon the theory that putrefaction of fish is first caused by bone taint, due to the fact that in the old methods of curing fish the specific or animal heat is partially left within the fish. The new method which has been introduced acts as a preventive to bone taint, completely removing the specific or animal heat from the fish to be cured.

Instead of salting, sun drying or shipping the fish in ice or refrigerating cars, the fish are dumped into a tank holding sea water which has been filtered through four cylinder-like tanks containing willow charcoal and screens to remove the noxious gases and foreign substances. Next, brown sugar is placed in the tank holding the fish to serve as a germicide for such organisms as may be active at freezing temperature. Then by refrigeration the temperature is lowered to 10 deg. Cent. below zero, during which time 16.1 per cent salt is added to prevent ice formation and to assist the formation of a thin protective coating over the fish themselves. Having allowed the fish to remain in this treatment for two hours they are ready for shipment, removed from the tank, and placed in the package or barrel to await transportation to market.

Antarctic Postage Stamps

AN interesting echo of Capt. Scott's antarctic expedition is the statement in the London *Times* that the British postal authorities are offering for sale all that are left of the special postage stamps issued for the benefit of the expedition, the proceeds to be used toward completing its work. Captain Scott was appointed by the government of New Zealand postmaster of Victoria Land, in the Antarctic, and Paymaster Francis Drake, R.N., assistant postmaster. There were, in all, three mails each way and one registered mail, carried by the "Terra Nova" from the base of the expedition in Victoria Land to New Zealand, or to other ships. All mails from the Antarctic bore the current penny and halfpenny stamps of New Zealand, surcharged. These now command at least 5 shillings and 25 shillings, respectively.

SIMPLE, SAFE AND SURE—the four principal features of the speedy little REDEMOTOR ENGINE. No gas engine experience needed. Runs on any adjustment of carburetor. Easy for a child to start, the

REDEMOTOR ENGINE

is absolutely safe and sure. Uses gas, gasoline, kerosene or alcohol. Runs fine on city gas. 3 sizes, ¼, ½ and 1 h.p. Silent running like an electric motor. Satisfaction guaranteed or money back. Write for Booklet 29C.

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12927) C. J. asks: 1. Does the speed that light travels vary in ether or a vacuum from its speed through the atmosphere? In calculating the distance of constellations and nebulae in light years is this variation in speed (if any) taken into consideration? A. The velocity of light in a vacuum, or the ether, is greater than it is in air in the ratio of 1 to 1.0003. This need not be taken into the account in determining the light years of the stars, because the air is only a few hundred miles in thickness at the most, and light requires less than a six hundredth of a second in traversing the earth's atmosphere. This is a vanishing quantity as compared with the time required for light to come from the nearest star. 2. Is the constellation known locally in Cuba as the "May Cross," because of its being visible better in that month, the true Southern Cross? What latitude farthest north can the true Southern Cross be seen at all from? A. The Southern Cross, the true Southern Cross, is highest in the evening sky in the month of May, so that it is seen farthest north on the earth in that month. Its principal star, α Crucis, is about 62 deg. south declination, so that it can be seen below 30 deg. of north latitude.

(12928) E. T. W. asks: We have men working at Bradley hammers, where the work is passed to them by a helper, so that they are compelled for hours at a time to look at metal near the white heat. We have provided heavy plate-glass shields to protect the men from flying sparks and hot scale. The writer has heard that mirrors have been constructed which were transparent from the back. The idea has been advanced that such a mirror could be used in this case and would reflect a large amount of the heat, at the same time enabling the operator to see the work. Have you ever published anything on the subject of making such a mirror? Do you know who could furnish such mirrors? A. Glass is silvered for mirrors and such a coating may be put on that it will be quite transparent, but will reflect much heat and light, thus to a degree protecting a workman who stands behind it. This process is described in our Supplement 1671, which we will send for ten cents. Should you wish to get a large plate silvered, you can probably have it done by John A. Brashear, Allegheny, Pa. This firm makes mirrors for telescopes. Perhaps the Pittsburgh Plate Glass Company could do the work cheaper.

(12929) C. W. P. asks: I shall probably soon need a camera for work in which a low-priced lens would be sufficient, however, there is a possibility that I may want to make stereopticon slides from the negatives, and would like to know your opinion as to what kind of camera lens would be satisfactory for such work. A. For making lantern slides a negative 3¼ x 4 inches is most convenient, since the slide can be made by contact, and a copying camera for reduction is thus rendered unnecessary A camera taking a picture of this size, 3¼ x 4 inches, is all that is required for making lantern slides, and the adjustment of the picture to the size of the opening of the mat, about 3 x 3 inches at the largest, can be made when the picture is taken. Now as to the lens, it is not good economy to use a cheap lens The better the lens the better the work, the sharper the focus, the flatter the field, and the focus at the edges of the field. With a cheap lens the edges of the field cannot be in as good focus as the center. You would better have a cheap, home-made camera and a good lens than the best camera and a cheap lens.

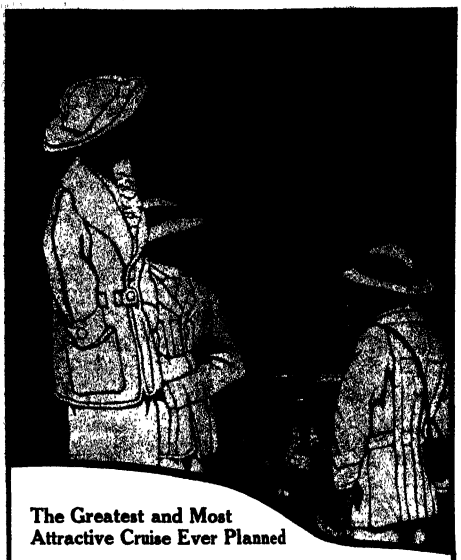
(12930) E. F. asks: I am in receipt of your letter of November 19th, and note that you say that "the air nearby may be somewhat above 32 deg." As a matter of fact, I have seen frost when the temperature of the air several feet above ground was as high as 36 and 38 deg. Several nights during the early fall, when the temperature did not go below 36 deg., there was still a heavy covering of frost, due to the rapid radiation of heat from the ground, and the consequent lowering of temperature of the dew below the freezing point I wanted to know whether any experiments had been made to determine whether frost formed at a still higher temperature than that observed by me. I desire to thank you for your reply to my last letter, and if you have any further information on the subject, kindly advise me. A. As we wrote you before, the temperature at the point where frost forms must be 32 deg. Fahr. What the temperature may be a few feet or a few inches away no one can say. The air is a non-conductor of heat. If the air is still, it may be higher than 32 deg. very near the place where frost is forming. We have many times formed frost in a room where the thermometer was above 70 deg. Fahr. by evaporation of a volatile liquid. If the air is in motion the temperature in the neighborhood of the frost will not differ perceptibly from 32 deg. Fahr. We do not see how any exact statement of temperature as you desire can be made.

(12931) G. T. S. asks: A friend of mine has an agate which he found on the Oregon coast, and one surface of which he has had polished. There is an opening in the agate about an inch long, and this opening is partially filled with water. Will you kindly let me know through your Notes and Queries columns how this water got inside the agate? A. The mode in which an agate is probably formed will explain the occurrence of water included in some of these stones. It is probable that there existed a small pocket or crack in the rock. Water holding silica in solution worked its way into this cavity and deposited a layer of silica. This was repeated for a long time, until the agates in layers resulted. If the agate formed in a spherical or rounded cavity, the result might easily be that water would be inclosed in the completed stone The water might be nearly invisible if the cavity was completely filled; but if a space was left unfilled, the water could be seen as the stone was shaken. This is the theory held by mineralogists to account for the frequent inclusion of water in such crystalline stones.

(12932) L. G. B. asks: Given one large jar of water, and another of mercury, both at the same temperature, and immerse in each the bulb of a thermometer cooled to 20 degrees below the temperature of the water and mercury, will the temperature of both thermometers rise 20 degrees in the same time? A. The thermometer will rise more rapidly in mercury than in water. Mercury is a metal, and metals are better conductors of heat than are the non-metals. Indeed, water is one of the poorest conductors of heat. It is usually heated by convection. 2 Will you please give an exact and absolute definition of temperature? I have an elaborate modern treatise on heat, the first chapter of which is devoted to temperature, without, however, defining it. A. Temperature is the thermal condition of a body which determines the transfer of heat between it and other bodies. It is therefore the relative intensity of the bodies in relation to sensible heat, or heat which can affect a thermometer. Absolute temperature is simply temperature as referred to the absolute zero of the scientist. 3. Is it settled beyond dispute that a gas does not fall in temperature in expanding unless it does work? If so, what is the proof? A. It seems to be settled that a perfect gas would not fall in temperature in expanding. But a perfect gas is hard to find. Most gases are imperfect and are cooled slightly in expanding. Hydrogen is a pluperfect gas and is not cooled sufficiently by expanding Joule and Thomson's experiments are described in Poynting and Thomson's "Heat," page 296, "Internal Energy Taken Up by a Gas in Expanding" We will send the book for $4.25 postpaid. 4. If it does lose heat in expanding without doing work, what becomes of the heat? A The heat is used up in doing the work of expanding the gas, if it is lost from the gas 5. Does the statement that it takes nine times the quantity of heat to raise the temperature of a pound of water one degree that it takes to raise a pound of iron one degree, mean that all the heat applied in each case is completely absorbed? Or does it mean that the heat passes through and out of the water with only one ninth of the effect upon its temperature that it has on the iron? A. The specific heat of a substance is the quantity of heat actually required to raise a unit weight of that substance one degree as compared with the amount of heat required to raise unit weight of water one degree. The heat must all of it be absorbed by the substance. Iron will be heated about nine degrees by the quantity of heat which will heat the same weight of water one degree. Excepting hydrogen, water has the largest specific heat of any substance

(12933) E. F. S. asks: I would like to ask through your paper in regard to generating acetylene and under what pressure it will liquefy, and if any danger in using plunger pump to compress same? A. Acetylene is best generated by dropping the calcium carbide into a large quantity of water, since the heat of the chemical action is then taken up by the water. It cannot be liquefied at a temperature above 98 deg. Fahr At this temperature a pressure of 68 atmospheres, 1,020 pounds per square inch, is required to liquefy the gas. At the freezing point a pressure of 21.53 atmospheres, 323 pounds per square inch, will liquefy the gas. The explosions, which resulted in loss of life, from compressing the gas in cylinders, together with other troubles, stopped this mode of using it. At the present time it is dissolved in acetone, which will dissolve twenty-five times its own volume of acetylene at atmospheric pressure. It has proved safe to pump it into acetone You will find the information you require in Leeds and Butterfield's "Acetylene," which we send for $2.75 postpaid.

(12934) W. H. D. asks: At what temperature does water commence to expand before freezing condition exists, and up to what temperature does it get when ice forms? What is the comparative pressure per square inch of this expansion? A. The temperature of the maximum density of water is 4 deg. C., and from that temperature the water expands till at 0 deg C. it begins to change into ice. The corresponding degrees in Fahr. are 39.2 deg. for maximum density, and 32 deg. for the freezing point. The force of the expansion of water as it turns to ice is nearly 2,000 atmospheres. The volume of ice is about 0.09 greater than that of the water from which it is formed. Water is compressed 46 millionths for each atmosphere. To compress water 0.09 will therefore require 1,950 atmospheres. This is over 29,000 pounds per square inch.



The Greatest and Most Attractive Cruise Ever Planned

Leaving New York January 31, 1915, by S. S. CLEVELAND (17,000 tons) through the Canal, arriving at San Francisco in time for the opening of the Panama-Pacific Exposition.

This is the Safe and Sane Way to File Blue Prints

—the way to keep them clean, flat, smooth and findable instantly; the way to file your drawings, plans, sketches and all the big, unwieldy things you've got to keep handy somewhere.

Don't jam them into pigeon holes, don't shove them into big drawers, don't stand them behind your desk to get dirty and torn and—lost.

File them like letters. A "Y and E" Mammoth Vertical File will take care of 700 to 1000 prints properly and produce the one you want in a moment's time, and in as good condition as when it was put away.

Note the *index in the cover* Points out the location of the print you want

Note the front of the file; pulls out and two legs spring into place, forming a smooth, rigid table on which to examine drawings or make notations. Folds out of the way when you are through. The whole file when closed takes up floor space of 4 ft by 15 in

Made in two sizes—for drawings 40x36 or 44x30 ins. Prices. Plain Oak $43, Quartered Oak, $46, Mahogany, $60

NEW BOOKS, ETC.

THE ELECTRIC VEHICLE HAND-BOOK. By H. C. Cushing, Jr. and Frank W. Smith. New York: H. C. Cushing, Jr. 16mo.; 356 pp.; illustrated. Price, $2 net.

It is estimated by experts that almost ninety per cent of the gasoline trucks in use might profitably be replaced by the electric, with results all in favor of the latter The electric vehicle is on a very high plane of design, its builders having had the incalculable advantage of electric railway experience From a combination of unfortunate circumstances, they have had to make progress in popular favor in the face of great difficulty. This hand-book not only puts the case impartially, but informs the reader upon every conceivable point of equipment, operation, and cost. Estimates are given on the cost of various deliveries—parcel, city baggage, furniture, keg beer and coal. Owners and prospective purchasers will find the little work of great assistance

CHIPPEWA MUSIC. II. By Frances Densmore. Smithsonian Institution, Bureau of American Ethnology, Bulletin 53. Washington: Government Printing Office, 1913. 8vo.; 341 pp.; illustrated.

Bulletin 53 is a supplementary volume to Bulletin 45, and continues Miss Densmore's studies of Chippewa, or Ojibwa, music, particularly in its relation to tribal life. There are songs of their games and their dances, songs "composed in dreams," and those of the famous drum-presentation ceremony are given, with description. In the present volume the melodic and rhythmic analysis of the music is continued. The Rev. C H Beaulieu, a member of the tribe, is responsible for the analysis of the words and for a part of the translation

HAND-BOOK OF TEXTILE CORPORATIONS. 1913. New York. Frank P. Bennett & Co., Inc. 8vo.; 744 pp.

The hand-book is compiled for the benefit of three classes of readers—the bankers, the brokers, and the investing public—and is sold with the understanding that purchasers may make unlimited inquiries about the finances, equipment, production, etc., of the listed mills. The work is a co-operative compilation, in that it has received information and aid from bankers and from the manufacturers themselves The result is an authentic reference volume giving the location, capital, officers, production, power, and markets of every textile mill in the country

PRACTICAL USES OF THE WAVE METER IN WIRELESS TELEGRAPHY. By J O. Mauborgne, First Lieutenant 24th U. S. Infantry New York: McGraw-Hill Book Company, Inc., 1913. 8vo.; 74 pp.; with diagrams. Price, $1 net.

The basis of this work has been used as a reference text at the Army Signal School, Fort Leavenworth, Kansas, but in its amended form it is very well adapted for use in commercial and technical schools The book describes the types of wave meter used by the U S Signal Corps, explains how the meter is used as a receiving set, in measurements with the helium tube, and with the telephone, or galvanometer, and detector, and deals with sending-station tuning The final three chapters go with great detail into the measurements of damping, wave lengths, capacity, and inductance

ADVERTISING AND SELLING. Principles of Appeal and Response. By Harry L Hollingsworth, Instructor in Psychology in Columbia University; Lecturer in Business Psychology, School of Commerce, New York University. Published for the Advertising Men's League of New York City, Inc New York: D. Appleton & Co., 1913. 8vo.; 314 pp.; illustrated. Price, $2 net; by mail, $2.16.

We have often wondered why there was such a comparative dearth of books on the finer principles of advertising and salesmanship. Here is one that attacks the problem at its root, along known psychological principles dealing with and governing the arrest of attention Far from being academic, however, the work is intensely practical, and demonstrates its contentions by actual examples of present-day advertising. It goes further. It takes these examples and tabulates for us their results It takes various advertisements of the same goods, with the number of replies each brought, it thoroughly considers the incentives—mechanical and interest-catching Colors, types, relevant and irrelevant illustration are dwelt upon in their relation to attracting and holding the interest. No phase of the subject, no matter how remote or subtile, seems to have been overlooked The suggestions of the work should in many instances lead to a large increase of efficiency in the advertising and selling department.

GRAPHICS AND STRUCTURAL DESIGN. By H. D. Hess, M.E., Professor of Machine Design, Sibley College, Cornell University. New York. John Wiley & Sons, Inc., 1913. 8vo.; 428 pp; 429 figures. Price, $3 net.

This is a Cornell University text, in which the subject of structural design is broadly treated, the problems linking civil and mechanical engineering. The determination of stresses, it may be stated, is by no means confined to graphical means, as the title of the work might imply. The inclusion of a plate-girder railway bridge, though somewhat foreign to the spirit of the work, nevertheless serves the purpose of clarifying certain questions as no other illustration seems to do, besides pointing the use of the moment table. The volume may also find a field of usefulness as a reference book for designers.

BOSTON, MASS.

GROBET SWISS FILES
Are the standard of excellence in files, and have been for over 100 years We send postpaid as an introducer 48 files especially adapted for tool makers and machinists on receipt of $5.00 This is a chance to get a set of files you'll appreciate and we'll get future orders
MONTGOMERY & CO.
109 Fulton Street New York City

You May Crowd a CRESCENT JOINER
to the limit of capacity and the machine will do work just as smoothly as though you had not crowded it at all. Built in six sizes. Send for catalog telling all about them and describing our line of Band Saws, Saw Tables, Planers, Planers and Matchers, Shapers, Swing Saws, Borers, Disk Grinders, Variety Wood Workers.
THE CRESCENT MACHINE CO., 230 Main St., Leetonia, Ohio

STARRETT'S PLANER AND SHAPER GAGE
Will give any measure from ¼ to 5⅛ inches. Will accurately set cutter, planer or shaper tool to plane or mill any desired thickness without recourse to "cut and try" method As a plumb can be often used where nothing else is possible Great time and material saver. Price $3.75.
Send for 274 page catalog, No. 20-B.
THE L. S. STARRETT CO., Athol, Mass., U. S. A.

WELL DRILLING MACHINES
Over 70 sizes and styles, for drilling either deep or shallow wells in any kind of soil or rock. Mounted on wheels or on sills With engine or horse powers. Strong, simple and durable Any mechanic can operate them easily Send for catalog
WILLIAMS BROS., Ithaca, N. Y.

Cadillac
Standard of the World

Public attention is focusing upon one car

and especially upon a principle in that car which distinguishes it from others

Public attention is focusing upon one car, and especially upon a principle in that car which distinguishes it from other cars

The car is, as you will surmise, the Cadillac; and the principle is its two speed direct drive axle.

Partly because of that principle, the Cadillac rides differently, and, it is said, more luxuriously than most other cars.

The sales arguments of other makers tend to draw public attention in another direction—toward the more conventional types of construction

And in spite of that powerful influence upon public opinion, in Europe and in America—professional and public interest insists on returning to the Cadillac and its two speed direct drive axle

This is only logical—it is merely Cadillac history repeating itself, as in the three other memorable cases in which Cadillac progression altered the trend of motor car practice

The present tremendous interest in the 1914 Cadillac and in the splendid performances of the car can be traced directly to its source.

To begin with, more than 8,500 owners are now driving the 1914 Cadillac

More than 8,500 people expatiating with unbounded enthusiasm, day after day, upon the unique riding qualities resulting from the latest Cadillac development, are stimulating the keenest interest, even among those driving other cars

And this process growing and growing in volume, since the first of the new cars appeared last summer, received a pronounced impetus several weeks ago

The second award of the Dewar Trophy to the Cadillac was an extraordinary endorsement

Coming from the highest professional tribunal of its kind in the world—the Royal Automobile Club of Great Britain—it confirmed every Cadillac owner in his conviction that there never have been such riding qualities in any car

THE DEWAR TROPHY

That is exactly what Cadillac owners are saying—what the first owner you meet will say to you.

And these two things—the zealous partisanship of more than 8,500 owners rendered still more zealous by the Dewar award—are being accentuated by press comment at home and abroad.

That is why the united volume of attention attracted by other good cars and other good principles of construction have not been able to distract attention from this one car with its peculiar principle.

That is why American and European journalists are venturing to predict that the Cadillac has impressed a fourth indelible imprint upon the industry as a whole.

World-wide interest has been aroused by a plain and indisputable fact—that the sensation of riding in the new Cadillac is almost like the sensation of floating through space

All the technical and professional discussion in the world will not alter that extraordinary and delightful fact.

That is why we are impelled to caution you again.

If you wish to guard against disappointment, don't delay ordering your Cadillac.

You have been told the same thing, year after year. And year after year, with an annual increased production, the Cadillac supply has fallen short of the demand

If the qualities which won the Dewar Trophy—the qualities over which Cadillac owners are so ardently enthusiastic—the qualities which have become a topic of world-wide interest—are qualities worth getting in a motor car—see your Cadillac dealer at once.

Because these qualities are peculiar to the Cadillac

They flow out of Cadillac standardization, Cadillac methods, Cadillac ideals and the Cadillac two-speed direct drive axle.

It is these qualities, in short, which constitute the Cadillac the "Standard of the World."

STYLES AND PRICES

		Standard Touring Car, five passenger	$1975.00		
Seven passenger car	$2075.00	Roadster, two passenger	$1975.00	Inside drive Limousine, five passenger	$2800.00

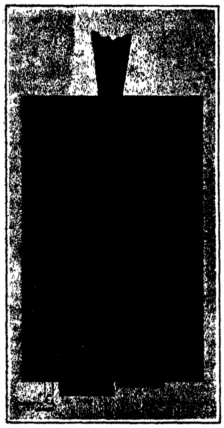
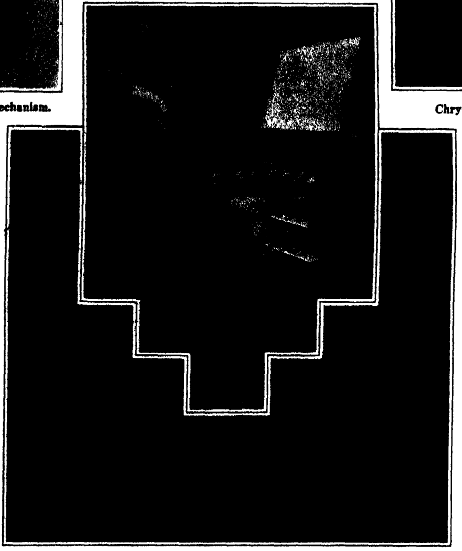
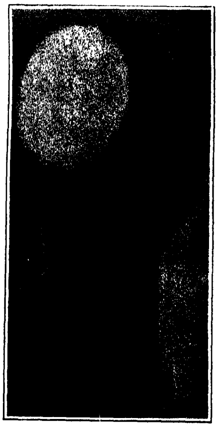
Chrysoglott with electric attachments.



Cross-section of wind chest and electro-pneumatic mechanism.



The inventor seated at movable console.
Wind chest with pipes.



Tambourines with vibrating device.

The Hope-Jones Unit Orchestra

By Moritz A. Jägendorf

IT took over twenty-three years to accomplish the work that changed the functions of an organ into that of an orchestra, and yet it appears to be very little when we consider for a moment the result. Thousands have listened to the unit-orchestra night after night in the New York Century theater, in the Cort theater of Chicago, and in perhaps ten more places in different parts of the country; also orders are said to have been received for many more in a number of States. The inventor of this wonderful instrument is Mr. Robert Hope-Jones, the famous electrician and organ builder of England.

Mr. Hope-Jones began his experiments as a hobby, and though it has now become his life work he still looks upon it with the same fondness as the one who does work for sheer pleasure. Naturally, he commenced this work on the organ. He began by placing all the movements in the organ under electrical control. This very soon showed that he could secure an action on the instrument that far exceeded the ordinary movement. But this did not satisfy him. As a musician, he felt that the musical qualities of the organ were not what they might be, and he therefore set out to improve them. Very soon he had a new invention that made possible a finer quality of tone and a larger variety of timbre. This was an apparatus for photographing sound waves in the atmosphere. With photographs of every conceivable instrument in every conceivable variety of tone, it was a comparatively easy matter to reproduce pipes whose notes were, if not exactly identical with those of the original, very near them. And when the percussive instruments that worked in harmony with organ pipes were added, it enabled the player to absolutely control the expression by hand and foot. It was now possible to reproduce the tones of the very finest musicians and the control of the instrument and its rapid action permitted the operator to produce music such as we associate with the very finest orchestras.

Previous to that Barker, an Englishman, had also worked out an arrangement that would control the speech of the organ by means of electricity, and had taken out patents covering his device. He also attempted, two or three times, a practical application of the invention both in England and in France. There were a few other organ builders who made similar attempts, but all of their inventions proved to be unreliable in action and soon fell into disfavor. The electro-pneumatic action invented by Mr. Hope-Jones was absolutely successful and popularized this method of control. It differed from the others, not so much because of a departure from the principle, but on account of the scientific perfection of its details.

On examining the Hope-Jones unit orchestra, there will be found first of all under every pipe, a long rectangular *valve A* set in a chest *B* that is supplied with compressed air furnished by means of a rotary fan driven at a speed of about 1,000 revolutions per minute. These valves are hinged on a pin *C* and are normally kept in their closed position by means of a wire spring *D*, as well as by the pressure of the compressed air in the chamber *B*. There is also a pneumatic bellows *E* so arranged that when closed it will, by means of the arm *F*, open the pallet or valve *A*. Under normal conditions the compressed air in the wind chest finds its way through the passages G^1 and G^2 into the interior of the pneumatic motor *E*, but when the double valve attached to the spindle *H* is raised the passage G^1 becomes closed and the compressed air within the motor *E* escapes to the atmosphere through the passage G^2. The pressure of the air in the wind chest *B* then collapses the pneumatic motor *E*, and by thus opening the valve *A*, allows the compressed air to escape by way of the chamber *I* into the organ pipe *J*.

(Concluded on page 150.)

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

More Information for the House Committee

ASSISTANT Secretary of the Navy Roosevelt, in a recent conversation with half a dozen captains of the United States Navy, asked them which they would rather command in the event of a fight between one "Wyoming" and ten "Oregons" Five of the six said they would prefer to take the "Wyoming." The sixth thought that he would take his chance with the ten "Oregons" because the one "Wyoming" *might* blow up Now this unanimous choice of the "Wyoming" was made for readily understood reasons The twelve 50-caliber 12-inch guns of the dreadnought would greatly outrange the old 35-caliber 13-inch guns of the "Oregons;" and the superior speed of the modern ship of 21 knots, as against the present speed of, say, 14½ knots of the "Oregons," would enable the "Wyoming" to maintain a distance of ten or twelve thousand yards, well beyond the effective range of the old 13-inch pieces, and silence or sink the ten "Oregons" one by one, or three or four at a time for that matter

It is considerations such as these that have led the naval powers to disregard the pre-dreadnought battleship, in estimating the strength of the first fighting line of modern navies, and it was sheer ignorance of these facts that led Mr Witherspoon of Mississippi in his recent examination of Secretary Daniels before the House Naval Affairs Committee, to make the ridiculous statement that the United States Navy is to-day superior in fighting strength to that of Germany, and also led him, alas! into a discreditable effort to repudiate the Navy Department's estimate of our relative battleship strength and charge our naval officers with having made a deliberately misleading comparison

The figures of dreadnought strength given in our editorial of December 20th, 1913, on "The Decline of the United States Navy," are perfectly correct When the ships now building are completed, England will have forty-two dreadnoughts, Germany twenty-six, and the United States twelve To-day, not even a dreadnought is considered fully available for the first fighting line, unless she has a speed of twenty knots or over, and if, when the ships now building are completed, we can put into our fighting line only twelve such ships against the twenty-six of the German navy, the enormous superiority of their first line of battle is established beyond all question

In pre-dreadnoughts, we are perhaps more powerful than Germany; but these, in the event of a first-class engagement, would on both sides be held as a reserve; no wise commander-in-chief would put them into the first line of battle, where they would hamper a dreadnought action by their much slower speed, their comparative lack of big long-range guns, and their comparative inability to withstand the gun and torpedo.

Germany could pit twelve dreadnoughts against our twelve and hold in reserve her other fourteen dreadnoughts; which later would enter absolutely fresh into the fight and quickly turn any advantage our fleet might have gained into crushing defeat

It is best to look facts squarely in the face, and realize, once and for all, that the opposition to warship construction of the past few years in Congress has meant the cutting down of construction at the very time when we should have been most active in meeting the new conditions presented by the evolution of the dreadnought. *It is this fatuous policy which has relegated* us to the position of a third-rate naval power Secretary Daniels, in the recent hearing, took a firm stand in favor of two battleships; indeed, if he is correctly reported, he stated that if he believed Congress would make the necessary appropriations, he would be in favor of recommending the construction of four battleships this year.

Bold international policies and an adequate dreadnought fighting line go hand in hand; and at no time were our policies so bold or so fraught with stupendous possibilities as to-day. Consider them: The Monroe Doctrine; the open door in the East; the integrity of China; Asiatic exclusion; and the preservation of the neutrality of the Panama Canal.

Flying Around the World

A FIRST PRIZE of one hundred thousand dollars for a trip around the world in an aeroplane! It seems worth winning. But is it?

An air journey of such length, a journey fraught with undreamed-of perils, may not be lightly undertaken—certainly not without much experimenting. Fifty thousand dollars would be a modest sum indeed to spend in designing, building and testing a machine, capable of flying around the world. Another $50,000 and more would probably vanish in dotting the globe with repair stations and fuel depots, each manned with highly paid mechanics And so the venturesome aviator would have to content himself with the $50,000 offered by Lord Northcliffe for a trans-Atlantic flight, a prize which he would also win by flying around the world. Even if his expenses were only $100,000, the winning of the Northcliffe prize would seem a wofully small reward for months of arduous preparation and ninety days of grave personal risk.

The Panama-Pacific Exposition directors must surely have realized all these difficulties, and so must the editors of the newspapers who have published yards *of printed matter on this romantic proposal.* Anyone with but an elementary knowledge of aviation, anyone who has read the difficulties that Védrines encountered in flying to Constantinople (German objections to flying over fortifications, the great wind surf of the Taurus Mountains, the shots of an ignorant, half civilized peasantry) must know that at the bottom of all this talk of flying around the world is a desire for so much free publicity

Suppose the feat could be performed What would be the good of it? It would not convince the tired New Yorker that the day is at hand when he may trundle out his monoplane as readily as his automobile and serenely soar off to some sanitarium in the Himalayas, where he may recuperate, thousands of miles from the bewildering attractions of a metropolis. Technically considered, the long trans-European and trans-Mediterranean flights recently made in Europe added only to the newspaper reputation of a few aviators, hungering for applause, but nothing to the technical advancement of the flying machine.

How much might be accomplished with the $300,000 so temptingly dangled in front of the noses of aerial acrobats! A whole aerodynamic laboratory might be built; a wonderful and highly instructive series of much needed experiments might be conducted which would illuminate the dark subject of aerial propellers; *an extremely valuable investigation of aeroplane motors* might be made, as proposed in last week's SCIENTIFIC AMERICAN. But of all this constructive work, of any true desire to develop the aeroplane so that it may become as safe and sure as the safest and surest of land vehicles—of all these wonderful opportunities not one is seized. Assuming that a supremely self-confident pilot seated at the wheel of a superbly constructed aeroplane, actually circumnavigates the globe, what will the world, the aviator, and the Panama Exposition be able to show for $300,000 spent to make an aviation holiday? Nothing but a battered machine and a battered man.

Early Developments in Naval Gunnery

A COUPLE of hundred years ago almost any ship capable of keeping the sea could be utilized as a man-of-war, and the simplicity of the armaments permitted a ready instruction of crews in the use of their weapons. It was customary, however, to build vessels specially for the purpose of fighting at sea. Ships of the line were constructed to carry heavy armaments and had thick sides to keep out the projectiles of those days. The discussions as to types best adapted for the various purposes of war were just as keen then as now

In fighting at sea it became customary to fire broadsides, or salvos, in order to permit the smoke to clear away before the next discharge, and to gain the advantage that the shock of the simultaneous impact of many projectiles produced on an adversary. The fighting was necessarily at close range, and positions of advantage were sought. That from which a raking fire could be delivered was the most to be desired, as from such a point a broadside could be opposed by but few guns mounted in the bow or stern of an enemy.

In the many histories of battles and of voyages published in those times, frequent [illegible] the methods in vogue of gunnery, target [illegible] tactics, all of which were matters of the [illegible] est at a time when fighting was not an [illegible] of a mariner's life. In fact, it would [illegible] state that naval gunnery was a matter [illegible] terest to the public at large at that [illegible] to-day.

In an account of Anson's wonderful voyage around the world in 1741-2-3, a description [illegible] taking of a Spanish galleon, off the Straits of San Bernardino, while on a voyage from Acapulco to Manila. The author tells of the gunnery methods [illegible] this occasion to defeat the Spaniards, [illegible] to fire broadsides and to lie flat on deck [illegible] ing a salvo from an enemy. Anson, who was short handed, surprised the crew of the [illegible] sion, and, greatly to their discomfi[illegible] individually and in succession. Pick[illegible] piece to piece for the purpose of dire[illegible] them, while the guns were loaded b[illegible] solely for that purpose. The smooth[illegible] period were fired point blank, by m[illegible] match and the use of the powder hor[illegible]

Rodney's memorable victory of Apr[illegible] been ascribed to the flint locks fitte[illegible] the "Duke," out of his own funds, b[illegible] that vessel of the previous year. The [illegible] this ship forced the opening of the ga[illegible] line which so materially contributed t[illegible] that occasion.

Shortly after this time "quarter sight[illegible] guns. These were marks engraved on [illegible] base ring of the piece. Graduations [illegible] degrees from point blank to an eleva[illegible] three degrees, and they permitted a rou[illegible] for a variation in range.

During the War of 1812 the guns of Am[illegible] were generally fitted with adjustable sights. British authorities of this period have ascribed the successes of their adversaries at sea to this feature, as they themselves had not then adopted those devices, which were considered to be objectionable because of the probability of their fouling the ropes and gear of a sailing vessel, and because of the large port openings made necessary by their use. The "Shannon," at the time of her victory considered to be the best gunnery ship in the British service, was a notable exception to the British rule, and had adjustable sights. During this conflict several actions resulted in American [illegible] because of the fact that our vessels were generally armed with long guns which permitted an accurate fire when our ships were still beyond the range of the shorter weapons of our enemies.

The smoke of the discharge of salvos was a great detriment to rapid gunnery then as now, smokeless powder having diminished but not entirely eliminated this difficulty. In order to overcome this obstacle, and to permit firing when the ship rolled in a seaway with the target close aboard, but shrouded in smoke, an ingenious expedient of utilizing a large pendulum hung in the main hatch was adopted. A system of signals or orders was devised as a part of the fire control scheme by means of which directions were given regarding the proper angle of elevation for the lee guns, or of the depression necessary for those of the weather side, which enabled the guns of the broadside or broadsides that were engaged to be fired when horizontal. This device was also used by the British frigate "Shannon" during the War of 1812-13.

The always highly technical French gunners improved the pendulum idea by checking the indications on this apparatus by means of a reflecting instrument showing the coincidence of the real and reflected horizon at the instant at which the axis of the gun became horizontal.

The advent of the rifled gun, which permitted greater accuracy and penetration of the projectile, was a great step in advance for gunnery as well as ordnance. Iron breech-loading rifled guns for discharging shell were invented in Europe in 1846. The adaptation of breech loading to rifled cannon permitted greater ease, safety, and speed of loading and greatly improved the accuracy of fire, and was another great advancement in the science of gunnery.

Another important stride from the standpoint of ordnance was the invention of the turret. The turret was first given a practical trial on board the "Monitor" (built by Ericsson) in her historic battle with the "Merrimac" at Hampton Roads, and it is distinctly an American contribution to the naval art. The advantages of turrets were that they afforded a good protection and provided a wide arc of fire for the gun. Out of the turret has grown the "dreadnought."

The naval telescope sight, invented by Lieutenant, now Rear Admiral, Fiske, and demonstrated by him at target practice in 1892, was a most important improvement in naval ordnance. The telescopic sight, the range finder and the spotter have made possible the marvelous accuracy of modern long-range shooting.

Engineering

Bering Coal Fails in Test.—Coal taken from the Bering River field in Alaska and tested in the American navy to determine its fitness was a complete failure. This has proved a great disappointment to officials of the navy, who realize that the results of these tests have an important bearing upon the question of the future coal supply of the navy in Pacific waters.

Oil Supply for the Navy.—With only a portion of the fleet equipped to burn fuel oil, the navy is now using 30,000,000 gallons of fuel oil per year, and, according to the Secretary, the time will soon come when the annual amount required will be 125,000,000 gallons. It is proposed to establish tanks at various ports and strategical points; and a special board is investigating the oil lands of the Osage Indians in Oklahoma with a view to their purchase for naval supply.

France to Build 16-Gun Dreadnoughts.—On January 1st, 1915, the French Admiralty will commence the construction of four super-dreadnoughts of about 29,000 tons, which will each carry sixteen 13.4-inch guns in four quadruple turrets. These ships will be able to fire eight guns ahead, eight astern and sixteen on each broadside. The French believe that these ships will be superior to the British "Queen Elizabeth" type, which can concentrate half the number of 15-inch guns in the several directions of fire, or four ahead and astern and eight on each broadside.

Canal Excavation in December.—The grand total of canal excavation to January 1st, 1914, was 215,458,272 cubic yards, leaving to be excavated 16,894,728 cubic yards. The total excavation for the month of December was 1,581,726 cubic yards. In the central division, including Culebra, the total was 860,429 cubic yards, of which 161,000 cubic yards was removed by steam shovels from the top of the banks of Culebra cut in the zone of the slides, in order to relieve pressure, 417,807 cubic yards were taken out of the slides, and 141,000 cubic yards removed by the Culebra sluicing plant.

Perilous Railroad Track.—The Interstate Commerce Commission's report on a derailment on the St. Louis & San Francisco Railroad revealed abominable conditions of the track at the point of derailment. Says the report, the state of the track "was such as to constitute a dangerous menace to the operation of trains in safety." At a rail joint near the point of derailment three spikes were so loose they could be removed by hand, and two rail joints were bolted on one end only. Nine hundred feet east of the point of derailment a rail section was found, under which ten out of the twenty ties were decayed, and a total of thirty spikes were removed by hand from the ties under this rail section alone. Could matters be much worse than this?

Proposed Navy Armor Plant.—The Chief of the Bureau of Ordnance, Rear-Admiral Joseph Strauss, submitted figures to the House Committee on Naval Repairs showing that to build a plant for the construction of armor with a capacity of 16,000 tons a year would cost about $11,000,000. The above-mentioned amount would be necessary if the standard of two additional battleships a year were followed. The witness stated that the construction of this plant would be a wise policy, since it would have the effect of enabling the Government to control the price of armor. Secretary Daniels is of the opinion that there is a "gentleman's understanding" among the armor-plate makers of the world to keep the price up to its present figure of something less than $500 per ton.

Deep Waterway from Montreal to Duluth.—The Government is favoring a discussion, through the International Joint Commission, of the proposal for joint construction by the Governments of the United States and Canada of a deep waterway for ocean-going steamers from Montreal to Duluth, Minn. The matter will be taken up first with the Canadian government. Various routes are proposed, costing from $100,000,000 to $300,000,000. The route favored provides for the utilization of all the lakes and of the St. Lawrence River. Shipment of the products of the Middle West from lake ports to the Atlantic coast and foreign ports, and a similar shipment of return cargoes, would be of vast benefit in reducing rail rates and improving rail facilities from all points to the ports affected.

A Ridiculous Proposal.—We are surprised to note that our staid contemporary, the *Tribune*, devotes nearly half a column to a statement sent "by telegraph to the *Tribune*," in which it is seriously affirmed that a Denver architect proposes to lift the "Titanic" by means of a multiplicity of magnets. A submarine is to be sent two miles down into the depths of the ocean, where it will direct the attachment of "powerful electric magnets" to the hull of the sunken ship. From these magnets light steel cables will lead to wrecking ships two miles above, at the surface. Here steam winches, when all is ready, will proceed to wind up the ill-fated ship and bring her to the surface. We think the technical editor must have been away from this desk when this Denver telegraphic dispatch found its way into print.

Science

An International Conference on Phytopathology is to be held in Rome February 24th, 1914, in accordance with arrangements made by the French government.

Destructive Earthquake in Peru.—An earthquake at Abancay, in southern Peru, on November 7, is reported to have destroyed many villages and entailed a loss of 200 lives.

The Centenary of the Discovery of Iodine was celebrated at Dijon, France, November 9. A commemorative tablet is to be placed on the house in Dijon in which Courtois, the discoverer of this element, was born.

The British Antarctic Expedition of 1914, under J. F. Stackhouse, will have a scientific staff of 40 or more, including two surgeons, two physicists, two geologists, an oceanographer, meteorologist, cartographer, hydrographer and biologist. It has not yet been decided whether wireless telegraphy will be included in the equipment.

The Nobel Literature Prize for 1913 has been awarded to the Indian poet, Rabindranath Tagore. Besides composing Bengali poetry, and his own translations of the same into English, he is a dramatist, historian, philosopher, and musician. One of his plays, "The Postoffice," was produced at the Court Theater, in London, last summer.

The Laws of Porto Rico are now available, in a bulky volume of 1,682 pages, just issued by the Bureau of Insular Affairs of the War Department. This notable work includes a compilation of the revised statutes and codes of Porto Rico, the acts of the Legislative Assembly (i. e., those of a permanent and general character) down to March 9, 1911, together with acts of Congress relating to Porto Rico and the treaty of peace with Spain.

Pictures by Cable.—According to a press report, Prof. Korn, who is well known to our readers as the inventor of the phototelegraph system reports that his invention has been so far perfected that he will be able to transmit messages across the ocean next year. He is planning to send pictures from Europe to New York and from New York to San Francisco at the opening of the Panama-Pacific Exposition.

Prof. Ferdinand Blumentritt, who died at Leitmeritz, Austria, September 20th, 1913, was probably the highest authority of his time on the Philippine Islands. He was so regarded by the Filipinos themselves, and his death is deplored by them as a national calamity; yet, strange to say, his knowledge of the islands was obtained entirely at second-hand, as he never set foot outside of Austria A monument is to be erected to him in the Philippines.

A Woman Explorer of Arabia.—A Russian woman, Countess Molitor, has just started on an attempt to cross Arabia at its widest part, from west to east, penetrating the desert of Roba'a-el-Khali. This huge desert is absolutely blank on the maps, has never been entered by a European, and is practically unknown even to the natives of adjoining parts of Arabia. The countess proposes to dress as an Arab and to be accompanied only by natives.

Centesimal Division of the Circle.—Most textbooks on trigonometry mention the suggested division of the right angle, or quadrant of a circle, into 100 parts, called "grades," each of which is divided into 100 centesimal minutes, and each of the latter into 100 centesimal seconds. According to the London *Times*, a bill will shortly be introduced in the French Chamber of Deputies to give legality to this substitute for the familiar sexagesimal system.

Sannikof Land, marked with an interrogation point on most North Polar maps, and supposed to lie due north of Kotelnoi Island, in the New Siberia group, was the principal objective point of Baron Toll's expedition in the "Zarya," 1900–1902, which cost the explorer his life. This land has been sighted by several explorers, since it was first seen, at a distance, by Sannikof, in 1811 According to *Petermanns Mitteilungen*, the rediscovery of this island was one of the fruits of Capt. Wilkitsky's (Vilkitskii's) remarkable expedition last summer, the capital achievement of which was the discovery of Nicholas II. Land.

Missing Arctic Expeditions.—Two arctic expeditions which sailed from Russia in the summer of 1912 have now not been heard from for so long a time that grave fears are felt for their safety. One, under Capt. Rusanov, after visiting Spitsbergen for the purpose of taking possession of some coal-fields on Bell Sound, attempted to proceed to Nova Zembla, but never reached there, so far as can be ascertained. The other, a large and well-equipped expedition under Lieut. Brussilov, sailed for the Kara Sea, intending to attempt the Northeast Passage to the Pacific, and to make extensive explorations all along the route. Provisions were carried for three years. Wreckage of a ship reported to have come ashore near the mouth of the Pechora River may indicate the fate of one or the other of these expeditions, and a steamer has been sent from Archangel to investigate.

Astronomy

Proper Motion and Distance of the Pleiades.—From a great number of observations it results that all the local groups of stars for which we have the necessary data are found to move in space very nearly parallel to the Milky Way. In each of these groups the parallelism of the movement is such that the parallaxes were determined. For the great majority of the stars they are easily comparable. Thus, for the stars, we know at the same time the position in space and the magnitude direction of linear movement. In investigating the mass of stars known as the Pleiades, they can be clearly divided into two groups, and in each of them the stars are sensibly more feeble than the normal magnitudes in corresponding groups. The question arises is there dispersion of light in a nebulous atmosphere surrounding the mass of stars? The question is at present very obscure.

High Potential Produced by Radium.—A radioactive substance which emits β radiations should, if isolated, acquire an increasing positive charge until a potential of the order of a million volts is obtained To verify this Mr. Moseley placed a small vessel containing radium emanation on a piece of quartz in the center of a flask which was highly exhausted A disk suspended from the neck of the flask by a quartz fiber formed a simple electrometer. It was found that a vessel of 9 millimeters in diameter attained a potential of 160,000 volts in a few minutes. A sudden discharge then took place across the residual gas in the flask. A vessel of 5 centimeters diameter becomes charged much more slowly, there is no discharge, and the final potential, 110,000 volts, is limited by a loss of electricity along the quartz support.

The Emptiness of Space.—When we speak of outer space, the space between star and star, as being empty of matter, it is rather interesting to see exactly what we mean We know from observations on the planets that light, in its passage across space to our earth, suffers hardly any absorption, and from this fact we can deduce conclusions respecting the density of such matter as exists in outer space. If the degree of rarefaction in outer space is, for example, in the neighborhood of the one hundred millionth part of an atmosphere, then the appearance of Jupiter, for instance, would be as if our atmosphere had twice its present opacity. So that such matter as exists must be in a much more rarefied state. But after all these terms are only comparative Suppose our atmosphere were allowed to expand up to the limits of the visible universe, as far as the Milky Way, then its rarefaction would be such that it would be quite impossible, by any optical means, to detect the presence of any matter. Nevertheless, there would be about five thousand molecules per cubic centimeter throughout space.

The Existence of the Ether.—The notion of a universal medium, permeating all space, has undergone many vicissitudes The sphere of celestial fire of the Alexandrians and the interstellar whirlpools of Descartes, gave way to the solid theory which was elaborated with immense skill by Young, Fresnel, Stokes and Kelvin, only to give way to the electromagnetic ether of Maxwell. At the present time there are at least three theories: one considers the ether as an incompressible medium, very rigid and very dense; another considers it composed of particles much smaller than electrons, and the third denies its existence altogether and seeks to eradicate it from the list of physical theories. It is this last theory which gains more and more adherants day by day We are in a revolutionary epoch, where the tendency is toward explaining phenomena in terms of emission rather than undulation, and of particles rather than fluids. And once more we see reappearing the mysterious and rather terrifying notion of the absolute "nothingness" of outer space which one imagined to be successfully abolished by the introduction of the ether.

Is the Sun Losing Mass?—The work of Einstein on the Principle of Relativity shows that a body which radiates energy loses a portion of its mass depending on the energy radiated. It follows that the sun, which continually radiates energy, is constantly losing mass. M. J. Bosler has calculated that the sun loses a mass equal to that of our earth in thirty million years. If it be assumed that the mass thus lost is gravitational mass it follows that the length of the year increases by six seconds in a million years, and that in the same time the mean longitude of the earth is affected in such a way as to produce a variation of one tenth of a year, i e., a retardation of thirty-six days in the seasons. Such variations are too minute to be observable. In stellar systems possessing a higher temperature the effect would be much more marked, for the energy radiated by a body varies as the fourth power of its absolute temperature If, as M. Nordmann believes, there exist stars having a temperature six or seven times that of our sun their radiation is one or two thousand times as intense. Thus, if the temperature of Algol is 13,800 degrees (Nordmann) it is calculated that at the end of two thousand years the eclipses of Algol suffer a retardation of about twelve minutes.

The New Curtiss Monoplane Flying Boat

IN the monoplane flying boat designed by Glenn H. Curtiss for Raymond V Morris of New Haven, features will be found that will be both approved and disapproved

In form the hydroplane hull suggests an expensive imported cigar; big at the end between your teeth, flat part of the way on one side, and tapering gently to nothing at the other end. Its principal dimensions are: length 22 feet; beam, 30 inches; depth, 36 inches. The bottom, as far back as the step, is the new double V type found in the new navy boats "C-3," "C-4," "C-5." The bow is pointed instead of square. Two holes in the hull permit the entrance of the pilot and, possibly, of one passenger. The pilot's seat is low, both to give him every protection from the wind, and to bring the shoulder yoke at the greatest diameter of the hull Unless the pilot sits up very straight only half of his head shows above the coaming

The wings are set about 40 inches above the hull, attached at the top to the welded steel structure supporting the engine bed, and braced below by struts extending to a cross beam which carries the balancing pontoons

The design of the wings is not unlike that of the European Etrich machine, and suggests a bird's wings The idea of placing the engine above the wings has been carried out before, notably in the Santos-Dumont machines. The position of the pilot, with such a weight above his head, is obviously dangerous. The total spread of the wings, from tip to tip of ailerons, is 34 feet. The spread of the supporting surface is 28 feet For 20 feet in the center the chord is 60 inches, while for four feet at each end the main surface is practically triangular.

Rudder, flippers, and rear stabilizing surfaces follow the lines of those used in standard models of the Curtiss flying boats, modified as to size to fit this smaller machine.

The machine was successfully tried out early in January.

The new Curtiss monoplane flying boat.

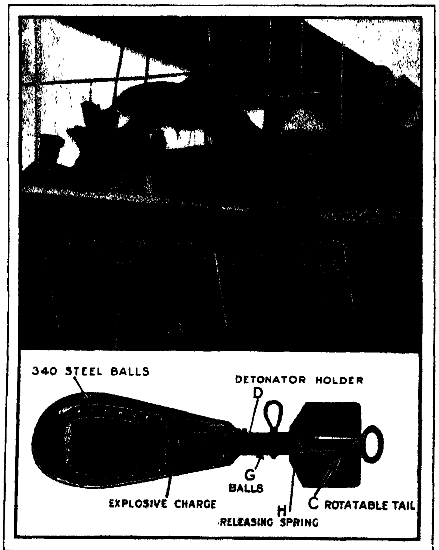
An Aeroplane Bomb That Explodes Only on Striking the Ground

THE new Marten-Hale aeroplane bomb, recently tested in England, has a very simple priming mechanism so that it can be carried in a magazine on board an aeroplane without danger of accidental explosion Should a bomb be hit while the aeroplane is in flight, or in case the aeroplane descended violently to the ground, by accident or otherwise, it is impossible for an explosion to take place. The bomb can explode only upon making a certain fall through the air and then striking the ground or other obstacle

At the top the bomb has a tail piece *C* rotatable by the air vanes The detonator holder *D* is held up away from the main charge by means of its collar and ball-bearing *G* held in place by the projecting end of a screw releasing spindle *H* When the bomb drops and the spindle rotates through the action of the vanes, it is screwed up until the projection moves away from the steel balls and allows them to fall inward, thus releasing the collar and the detonator. But the detonator still remains off the charge through the spring. When the bomb hits the ground, the detonator falls down on the charge and fires it, exploding the bomb in the customary way Such bombs can be dropped simply by hand from the aeroplane or can be fired by a spring gun in case a greater velocity is required

We illustrate a bomb of the shrapnel type, which has a total weight of 20 pounds and carries an explosive charge of about four pounds of trinitrotoluol. It has 340 steel balls, which weigh 5 pounds 12 ounces

A drop through at least 200 feet in the air is needed in order to cause the rotation of the tail end sufficient to give the release and arm the bomb as we have just seen, and as the firing mechanism is very sensitive, it gives an explosion upon the least impact even on water, mud, snow or the envelope of an airship. The angle of incidence can be as low as five degrees, as it is found. It is found that when dropped in any position from the aeroplane or at any speed of flight, the projectile soon takes the vertical position in falling, so as to hit the ground quite straight and end-on, and there is no tendency to somersaulting or wabbling in the air, which has been a source of trouble in other cases.



An aeroplane bomb that explodes only when it hits the ground.

Curing Noise in a Concrete Building

By E. P. Dorman

WITH buildings of concrete construction used for office purposes noise is often a very annoying feature, more especially so on floors devoted to general offices where large unbroken rooms occur, often sparsely furnished, and having relatively a few people working in them compared with the size of the room.

Under such conditions the sounds produced by people walking about, or shuffling their feet on the concrete floor, by typewriters, or even from talking, are greatly enhanced and echo very badly.

In a four-story building of reinforced concrete construction throughout, erected recently by an industrial corporation, for use exclusively as an administration building, the noise, particularly on one of the floors, was the greatest nuisance, it being at times well nigh an impossibility to hear what anyone said when talking over the telephone, and various expedients were tried during several months in an effort to remedy the trouble, without success. The main room on this floor is flanked on two sides by private offices used by the management, which were separated from the main office by partitions of wood and glass, carried up about eight feet from the floor

Notices were posted prohibiting whistling, loud talking, slamming doors, etc., which of course reduced the noise from these causes, but still left a good deal that was unavoidable. In another attempt to keep the noise out of the private offices, the partitions were carried clear to the ceiling, which is about 10 feet 6 inches from the floor. This form of partition, however, is by no means soundproof, and concrete floors and ceilings will transmit sound in spite of partitions.

Finally, after various other experiments had been tried, a professor from one of the leading universities, who is an authority on acoustics, was consulted. He advised putting down a square of carpet or a rug in the center of each of the private offices, and one or two in various spots in the main office.

His advice was followed, but in much the same frame of mind that must have been Cinderella's when, after listening to a glowing description of her coach and six horses, she was told to look for a pumpkin and six white mice.

The result in each case was a great surprise, however. The echo from the voice in talking has entirely disappeared, the office force no longer seems to be perpetually shuffling its feet at the desks, and the clicking from eight or ten typewriters, although they are situated on an uncarpeted part of the floor, is markedly subdued. The general sense of quiet is most noticeable, and this in an office through which there is constant passing from one department to another, to be added to the countless other noises that go to make up the general hum of an office.

It would seem that here lies one simple solution of the noise problem that is often advanced as one of the drawbacks to concrete construction for office buildings.

The German Observatory in Spitzbergen

AN account of the recent activities of the Spitzbergen institution, which was called into being by the Zeppelin-Hergesell expedition to Spitzbergen to study conditions with a view to an ultimate airship journey to the pole, is given by its director, Dr. Kurt Wegener, in *Petermanns Mitteilungen*. The observatory is located at Cross Bay, where the little staff of four men have erected their own buildings, viz., a two-story dwelling-house, a small balloon-house, a store-shed, and a rotating pavilion for the kite-winch. Besides the base station, there is a thermometer shelter at the top of the De la Brise Mountain (altitude, 2,000 feet), 4 miles distant, where temperature observations are made throughout the winter. The periodical ascents of this mountain afford an opportunity of observing the state of the sea-ice. An automatic tide-gage and a seismograph are kept in operation. Between June, 1912, and September, 1913, pilot balloons were sent up 270 times to determine the speed and direction of the upper air currents; the maximum altitude attained was over 8½ miles. Observations of temperature and humidity were obtained from 115 ascents of kites and captive balloons, up to a height of nearly 3½ miles. The observatory has a small outfit for wireless telegraphy, which exchanges messages with the powerful wireless station in southern Spitzbergen (this, in turn, being in regular communication with European stations). On one occasion the time signals sent out from the Eiffel Tower, 2,175 miles away, were received directly at the observatory, the longitude of which was thus determined with an accuracy unprecedented in the history of scientific stations in the Arctic regions. Lastly, some remarkable photogrammetric measurements of the altitude and distance of auroras have been made according to Störmer's method. The director of the observatory, with three men from the marble quarries at King's Bay, made a long sledge-journey into the interior in January, 1913, in a gallant effort to carry aid to the unfortunate Schröder-Stranz expedition.

Tokens of Changing China are seen in the immense increase of certain classes of imports into that country. In twelve years the annual consumption of kerosene has increased from 83,579,724 to 197,902,362 gallons, while the importation of lamps and lamp ware has trebled. During the same period machinery imports have increased from $1,000,000 to $3,000,000, with an additional item of nearly $1,000,000 for sewing machines. Matches and match making materials show an increase of over 300 per cent. Imports of clothing, hats, boots and shoes have increased tenfold.

Watching the World Revolve

IT was in 1851 that Léon Foucault ocularly demonstrated that the earth rotates. The occasion was one of historical interest. Foucault sent out invitations which were worded:

"You are invited to witness the earth revolve in the southern hall of the Paris Observatory, to-morrow, at half past two."

Since that invitation was extended, the experiment has been repeated many times. It has been described in the SCIENTIFIC AMERICAN whenever it was performed on a scale at all commensurate with that inaugurated by Foucault himself. Thus, some years ago, Prof. Forbes of Columbia University showed how the earth revolved in St. Paul's Chapel of Columbia University. On that occasion Prof. Forbes himself wrote an article for the SCIENTIFIC AMERICAN, in which the manner of conducting the experiment was described and illustrated.

Recently Prof. H. H. Turner of Oxford University repeated the experiment during the course of some juvenile lectures which he delivered at the Royal Institution. The Royal Institution is so important an organisation, and Prof. H. H. Turner so well known an astronomer, that naturally his lecture attracted not a little attention in the public press. Since the subject has thus once more been brought to attention it may not be amiss to set forth the principles of the experiment again.

Foucault suggested that a pendulum so suspended as to be free to swing in any vertical plane would ocularly demonstrate the earth's rotation. That this is so any reader can easily prove for himself. He has only to hold between the thumb and forefinger of one hand a thin cord to the bottom of which a fairly heavy weight is attached. As the weight swings the arm may be moved almost in any direction, without appreciably changing the plane of the pendulum's beat.

In the accompanying diagram let us suppose that *AB* is a straight horizontal rod from which the free pendulum *CD* is suspended in the manner indicated at *C*. Suppose the pendulum to be set swinging in the direction of the length of the rod *AB*, so that *D* remains throughout the oscillation vertically under the rod *AB*. If the rod *AB* be horizontally rotated in the manner indicated by the arrows, it will be found that the pendulum does not follow the rod, but continues to swing in the same plane as before.

It does not matter if the point *B* of the rod is fixed, and if the rod itself is shifted by moving the end *A* horizontally around *B* as a pivot. The pendulum still continues to swing in the same plane. This is true whatever may be the length of the rod. Hence it is clear that the same fixity of the plane of swing will be observed if the rod be shifted horizontally as though forming part of a radial line from a point *E* in its length. In these cases the plane of the pendulum's swing will indeed be shifted bodily, but the direction of swing will still continue in the same plane.

Let POP' represent the polar axis of the earth; *ab* a horizontal rod at the pole bearing a pendulum as shown. If the earth is rotating about POP' in the direction shown by the arrow, the rod *ab* is being shifted round precisely as in the case previously considered. The swinging pendulum below it will not partake in its motion, and thus, through whatever arc the earth rotates, from west to east, the plane of swing of the pendulum will appear to travel from east to west under *ab*.

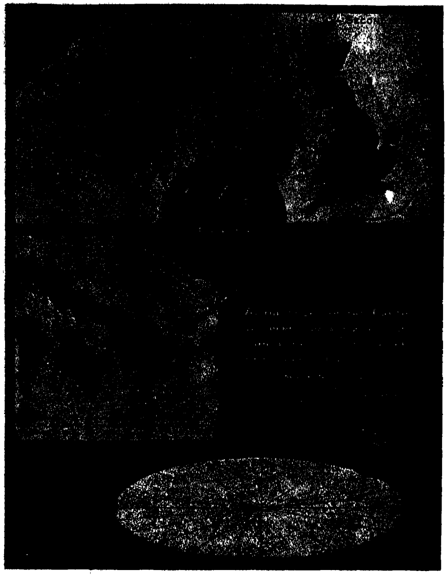
A pendulum, however, cannot easily be set up at the pole of the earth. The experiment must be conducted at a more convenient point. Suppose *AB* to be a pendulum-bearing rod, placed (for convenience of description merely) in a north and south position. Then it is clear that *AB* produced meets the polar axis produced (at *E*) and when, owing to the earth's rotation, the rod has been carried to the position $A'B'$, it still passes through the point *E*. Hence it has shifted through the angle AEA', a motion which corresponds to the case of the motion of *AB* (diagram) about the point *E*, and the plane of the pendulum's swing will therefore show a displacement equal to the angle AEA'. It will be seen at once that for a given arc of rotation the displacement is smaller in this case than in the former, since the angle AEA' is obviously less than the angle AKA'. In the latitude of New York a free pendulum would seem to shift through one degree in about five minutes.

It is obvious that a great deal depends on the mode of suspension. In Foucault's original mode of suspension, the upper end of the wire bearing the pendulum was fastened to a metal plate by means of a screw. It might be supposed that the torsion of the wire would appreciably affect the results. In reality, however, the torsion was very small.

It is usually customary to fasten a stylus to the bottom of the bob, which stylus, as the bob swings, plows through a layer of sand on a horizontal table. Spectators find it hard to believe that the pendulum is not swinging round toward the east, but that it is the table itself that is slowly and imperceptibly turning in the opposite direction.

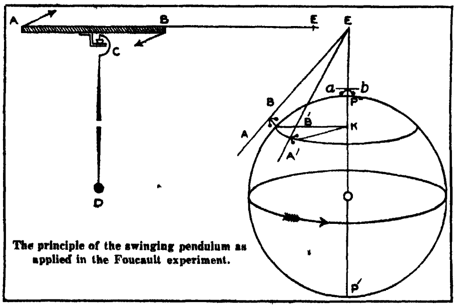
When Foucault made the experiment, he availed himself of the favorable physical conditions of the Pantheon in Paris. His pendulum weighed 62 pounds and was 210 feet long. It is necessary to use a massive sphere. The suspending wire is made as long as possible in order to get considerable linear with small angular displacement. Besides this, when the pendulum is long it swings slowly. This facilitates the readings.

The experiment is most easily understood if it is supposed to take place at one of the earth's poles, say the north pole. Here to an observer the earth would revolve horizontally from west to east. If at the pole the pendulum is set to vibrating in any direction with regard to space, a line drawn on the earth under the ball will rotate around the pole counter-clockwise, and complete its rotation under the plane of the swinging pendulum in 24 hours less 4 minutes (the sidereal day). The movement would therefore be about 15 degrees per hour. The desirability of position for the performance of the experiment diminishes as the equator is approached, at which place it is inoperative. The rule for determining the time of the complete rotation of the ground line is this: Divide 23 hours and 56 minutes by the sine of the angle of latitude where the experiment is being performed. For the latitude of New York city the time would be 36¾ hours. To get the distance the line moves per hour, divide 360 deg. by the time of the rotation of the ground line. For New York city it would be 9.8 deg.

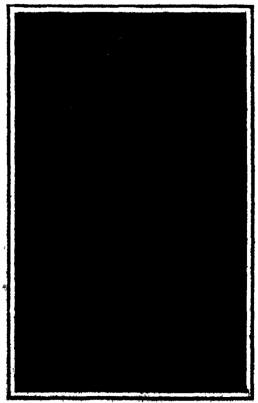


By courtesy of the *Illustrated London News*.

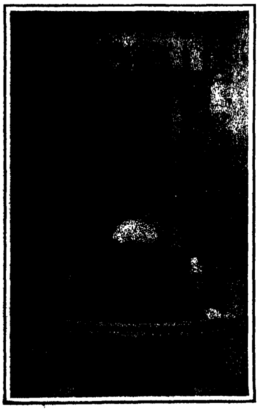
The famous experiment of Foucault.



The principle of the swinging pendulum as applied in the Foucault experiment.



The pendulum is usually started by burning the thread. The pendulum is brought to rest by gravity and resistance of air.



In repeating the Foucault experiment Prof. Forbes used an electrical device to keep the pendulum vibrating for any time.

◆

The Only Lacrosse Stick Factory in the World is located at Cornwall, Ontario, according to a consular report from that place. The game originated in that region, and the Indians thereabout have special skill in whittling the handles of the sticks. The factory employs ten Indians, most of whom will work only in winter. Three fourths of the product is consumed in Canada, the rest going to the United Kingdom, Australia, and New Zealand, except about one per cent which is sent to the United States—principally to the Carlisle Indian School and Ithaca, N. Y. About $2,000 worth of hickory wood for the sticks is annually imported from the United States, while the gut comes from England.

What Machine Has Displaced the Greatest Number of Men?

To the Editor of the SCIENTIFIC AMERICAN:

We would like to have the name, or some slight information, regarding the machine or machines which has displaced the greatest number of men, and where we would be most likely to see one.

We have been told that it is a shoe machine, but as we want to know for business purposes, must have authentic knowledge, and we know your word is final.

Your favor in this matter will be greatly appreciated.

Philadelphia, Pa. J. J. GEISINGER COMPANY.

[The question here raised is most interesting. Perhaps our readers will let us have their views.—EDITOR.]

The First Wireless Time Service

To the Editor of the SCIENTIFIC AMERICAN:

In my article on the wireless time service of Beloit College, which was published in the issue of January 24th, the claim was made that it was the first of its kind in this country. Since writing that article it has come to my notice that the United States Navy has been operating such a service since 1905 and should, therefore, be given full credit for being the pioneer in the field, not alone in this country, but in the world. It is all the more a pleasure to acknowledge the priority of the Navy because in that early day radio telegraphic appliances were by no means so well developed as at present. E. A. FATH.

Beloit, Wis.

How to Fly Across the Atlantic

To the Editor of the SCIENTIFIC AMERICAN:

In the SCIENTIFIC AMERICAN of December 27th, 1913, Mr. Henry Harrison Suplee gives his ideas of "How the Atlantic could be most easily crossed in an aeroplane." Others in Europe have suggested different routes, but never have I seen suggested the route I am going to mention, and that seems to me the most practicable because of the short stages of the trip and of the weather conditions.

	Kilometers
Tarfaya, west coast of Africa, to Lanzarote Island (Canary route)	150
Lanzarote to Funchal (Madeira)	470
Funchal to San Miguel (Azores)	800
San Miguel to Fayal (Azores)	290
Fayal to Santa Cruz (Azores)	260
Santa Cruz to St. John (Newfoundland)	1,800
	3,770

The distances are approximate.

The longest distance, 1,800 kilometers, could be divided in two stages by having a station ship located midway.

Aeroplanes will easily speed at 60 miles an hour (98 kilometers), then the longest stage (900 kilometers) would be covered in nine and one half hours. This has been made before.

By making several stops at the Canaries, Madeira and Azores islands, the stages could still be reduced in length.

Mr. Harrison Suplee's suggestion of a northern route would freeze any aviator traveling at the rate of 60 miles an hour. J. ARMENDAIZ.

Alpine, Tex.

[Our correspondent forgets that the Atlantic would be crossed at a height well above 2,000 feet, and that at great altitudes there is little difference in temperature between the frigid and torrid zones of the earth.—EDITOR.]

The Zuider Zee and the East River

To the Editor of the SCIENTIFIC AMERICAN:

Mr Hiehl's article on the partial draining of the Zuider Zee in your issue of January 24th, naturally appealed to me with unusual interest, seeing that it was after reading an account of this same gigantic project in *McClure's Magazine* of October, 1903, by Mr Walter Wellman, that the idea occurred to me of filling in the East River by the application of the same method of engineering as that proposed in Holland, my proposal being contained in a letter which appeared in the SCIENTIFIC AMERICAN SUPPLEMENT of July 9th, 1904. Quite recently I have seen it stated that a plan to obliterate the East River was first made some fifty or sixty years ago, but up to the present I must confess to being unable to verify this very broad and indefinite assertion. Perhaps, however, some reader of your paper may be in a position to throw light upon the point in question, and to say who originated the plan, besides giving the actual date and means to be employed.

It certainly argues much for the forethought, resolution, and enterprise of the Dutch character that a work of such unparalleled dimensions and difficulties as the reclamation of the Zuider Zee should have been at length decided on by the States General. Whether in like manner the project of turning the East River into dry land will be adopted is a problem that perhaps will be reserved for a future generation of Americans. At any rate, it has found much favor during the last ten years with several noted engineers, as repeated articles in the New York press during that time bear testimony.

Arrangement of Magneto Magnets

To the Editor of the SCIENTIFIC AMERICAN:

In reading the account of your associate editor's trip through the Ford Motor Company's factory, in the SCIENTIFIC AMERICAN of January 8th, on page 9, column 3, lines 8, 9, and 10, I note the following error in stating the method of placing the magnets in trays:

"With the north pole of one magnet touching the south pole of the next adjacent magnet, and so on."

This should read, "with the north pole of one magnet touching the north pole of next adjacent magnet, and south pole of same magnet touching south pole of next adjacent magnet, and so on." The magnets should be placed in tray so as to have no attraction for each other. Thus the two north poles constitute a positive pole in the magneto, and the two south poles constitute a negative pole, hence their alternating current.

I think this should be corrected in your columns, as it will mislead those not familiar with magnetism, and those who might be saving that part as instruction in replacing the magnets on their Ford cars.

ROBERT L. WHITCOMB.

Memphis, Tenn. Supt. Memphis Assembling Plant.

The "Nevada" and the "Queen Elizabeth"

To the Editor of the SCIENTIFIC AMERICAN:

I have been much interested in the recent discussion as to the offensive and defensive qualities of the 25-knot dreadnoughts of the "Queen Elizabeth" type and our "Nevada" type. The information given us in the SCIENTIFIC AMERICAN is not sufficient to enable one to determine which of the two types will prove the more effective all-around ships. I believe, however, if it were possible to obtain the full details showing displacement, fuel carrying capacity, kind of fuel, speed, radius of action, armor protection, torpedo defenses, etc., that the differences in favor of either ship would be immaterial.

To my mind, the prime requisite quality of a fighting ship of to-day is the ability to concentrate an irresistible attack. You have told us that the result of target practice in the British and American fleets was about the same, namely, forty per cent, until the fire control system was installed in the British ships, increasing their efficiency more than 50 per cent. This, to my mind, is where the British ship is superior to ours. You have told us that, in view of the increased efficiency by reason of this fire control system in the British ship, theoretically one round from said ship would either sink our "Pennsylvania" or so cripple her that she would have to retire from the scene of action. Consequently, there is only one conclusion I can come to: regardless of the fact that the "Nevada" could train two more guns than the British ship, she would be subjected to a preponderance of force that would be irresistible.

I would be much interested to learn more definitely showing a superiority in some way or another in our "Nevada" type sufficient to compensate us for the extra speed and the superior means of concentrating an attack in the British ship. R. DANIELS, JR.

New York city.

[By "fire control system" our correspondent, we think, must have in mind Admiral Scott's "director system," by which the target practice of the British fleet was improved over 100 per cent.—EDITOR.]

The Relation of the Ant, Leaf Roller and Spider With Bark Diseases

To the Editor of the SCIENTIFIC AMERICAN:

So many things have been attributed to the chestnut and other bark diseases that most people are apt to regard anything new respecting them as of little consequence. My experience, however, may throw a new light on this subject. It is a well known fact that the ant, aphide and the spider live together; this has been established by entomologists. Of the leaf roller, however, little seems to be known. Does the ant take care of this insect also, and what is his part in the disease?

I have found by carefully examining this insect and watching his development during the past summer, that the leaf roller is really the enemy of the tree. The way this is produced is very interesting. First, the spider and the ant take the leaf roller up the tree—in what numbers I do not know. But here the leaf roller begins his work, always guarded by the spider, and, strange as it may seem, this leaf roller lives entirely on the spider's web. This is done early in spring. The leaf roller makes a house for the aphide in the curled leaf of the chestnut which follows the ant, and is the first to appear in early spring; then come the others. I carefully put this leaf roller away in spring to develop. However, there was no development, and I was at sea to know what he was until one day in October I was looking for new evidence when I came across several of these leaf rollers. I tried to develop them again, and, to my surprise, I found out that the bottle I put these leaf rollers in was alive with small sucking insects which came from the leaf roller's body. Having discovered this, I compared them with the insects taken from the swelling of the tree and they proved to be the same in every case. These insects girdle the tree and go under the bark a distance of one and a half inches so that no spray will ever touch them or destroy them, and there is no hope for the tree unless these insects are kept from going up in spring. Once affected the tree is sure to die. That the ant is at the bottom of all this there seems to be no question. It is said that a live culture of this disease has been made. I think that this would be possible as the insects are like so much dust. We have F. R. Meyer's report that he has found this disease in China. If this is true, why does it not kill trees in China? Then come reports from India that the ants are killing the trees out there. If this is true, then why can the ant not kill trees in the United States of America? ARTHUR LAVIN.

Bernardsville, N. J.

Bacterial Versus Inorganic Fertilizers

To the Editor of the SCIENTIFIC AMERICAN:

I read in your issue of January 24th an interesting letter by R. W. Davis of Moline, Ill., about "Bacterial versus Inorganic Fertilizers for the Soil." Mr. Davis takes issue with Mr. Cahill's statement that the artificial fixation of atmospheric nitrogen is one of the ten greatest inventions, especially in its relation to agriculture. He claims that this discovery is not important to agriculture because nitrogen is so easily obtained from the atmosphere through certain bacteria found on the roots of leguminous plants.

Now we all know that leguminous plants are a very fruitful source of nitrogen, but it is a very slow and a very hazardous process of obtaining it. If a leguminous crop could be grown as easily as weeds and with as much certainty, it would be another question. But this is not the case. It requires not only that the soil shall be in good mechanical condition, but good seed, and especially freedom from thawing and freezing, which destroys leguminous crops, especially alfalfa and clover.

Peas, beans and vetch planted in an orchard may supply the necessary nitrogen because fruit trees, as a rule, do not require as much nitrogen, and because they are feeding a good share of the time. They are permanent in the soil, but this is not true of the great family of hoed crops like corn, potatoes, cabbages, and small grains which mature inside of 120 days, and which require the bulk of their plant food within 60 days of the growing period. They must have nitrogen then or never.

Abroad and in the eastern part of this country they do not depend upon leguminous plants to supply the nitrogen for the staple crops, and never will. It is true that commercial fertilizers do not supply any considerable amount of organic matter, but this can be kept up by applications of stable manure and by growing catch crops or cover crops which can be plowed in from time to time.

From Mr. Davis' point of view we would not be justified in even utilizing the by-product nitrogen of our industries, the by-product nitrogen obtained from tankages, seed meals and fish waste. Is it not well to conserve this nitrogen and apply it to the soil, much of which has come out of the soil in the shape of crops which have been fed to animals? Also the enormous amount which is obtained in the shape of sulphate of ammonia from the soft coals which are used for coking purposes? Right under a good share of Illinois, in which Mr. Davis lives, there is a vast amount of nitrogen stored up, which some day will be utilized. Again, is it not well to utilize the thousands of horse-power going to waste in our great waterfalls, in creating electric energy with which to extract the nitrogen from the air, which in turn may be applied to the soil of Illinois to restore the nitrogen which has been exported in cereals all along the line of conservation.

We are doing it now in the cyanamid of which you speak in your editorial comments, also in the nitrate of lime made in Norway; and it is confidently expected that we are going to do it by some catalytic process which may be either exothermic or endothermic. It is predicted that some day nitrogen will be as cheap as phosphorus and potash, but whether it is or not, the commercial farmer will not wait upon the slow and uncertain process of obtaining atmospheric nitrogen through leguminous crops; that is, if we may judge by the growth of the fertilizer industry, both in Europe and in this country in the past ten years.

Crew of turret on "North Dakota" which won the E (excellent) badge.

SINCE the beginning of our history the United States has always led in the development and advance of gunnery; an exception being during that period which followed the Civil War, when our position changed from that of the leading naval power among the nations of the earth to that of one of the weakest. During that period of retrogression certain officers remained alive to the needs of the navy with respect to gunnery; but lack of appropriations and a flagging interest on the part of the country in naval matters, together with a deep-rooted conservatism on the part of individuals, stood in the way of progress.

A volume of considerable size was published in 1886 by the Navy Department on the "Target Practice of the Vessels on the North Atlantic Station," in which appears an effort to arouse the interest of the service in this matter. The volume lays down a course of training and "Rules for Fire." The principles given were essentially those of today. In the training recommended, "sub-caliber" was an important feature, a small arms rifle being attached to the larger piece and fired at a target at a reduced range. All sights were set together as ordered by the gunnery officer, and the guns were fired in succession or in salvo, the fire being controlled by an officer aloft.

But little real progress in promoting interest in gunnery was made for some years; a revival began, however, with the reconstruction of our navy; and while the marksmanship during the Spanish-American war did not compare with that of to-day, the gunnery of the few vessels then composing our battle fleet was probably not inferior to that of any navy of the world at that time.

The methods of training inaugurated by the well-known English officer, Admiral Sir Percy Scott, came to the notice of Capt. W. S. Sims, then a lieutenant of many years standing, about 1901. Sims put his shoulder to the wheel, and, supported directly by President Roosevelt, he overcame the departmental inertia and established for us a definite plan for gunnery work and training.

"Idaho" repelling torpedo attack at night.

For years previous to this time target practice had been under the control of the Bureau of Ordnance, which was also charged with the design and supply of materials. An annual allowance of ammunition was authorized for target purposes, but no definite plans for practice were drawn up, and the ammunition for testing of materials and the training of crews was not always expended to the best advantage.

It is obvious that this system was defective and could not make for progress The office of the inspector of target practice was established in 1901 under the Bureau of Navigation, and it remained there until taken over by the Division of Operations of the Fleet.

In 1896 a shot every three minutes from a turret gun, and one a minute from a six-inch weapon were considered to be satisfactory performances A good "line shot," but "a little short" or "over," was very common and accepted as satisfactory comment at target practice. It has been calculated that we made about 3½ per cent of hits at the battle of Santiago at a range of about 3,000 yards Most of these were with the smaller guns How different the results of to-day, when more than three hits a minute are made from 12-inch guns, and eight are not infrequent from those of 6 inches in caliber. In the spring of 1911 the "San Marcos" was destroyed in a very short time by the guns of the "New Hampshire" firing at a range of about six miles The percentage of hits was a sufficient demonstration of improvement and of the progress up to that time.

In the beginning of our modern development, and for some time after the establishment of the Target Practice Office, target firing was held in smooth water, at measured ranges. These conditions obtained for several years. Defects in material were discovered and remedied, and officers and men were schooled in the elements and principles of gunnery.

In the practice of to-day realism is sought. Firing takes place under battle conditions, as closely as they may be simulated, and with regard for the casualties to be expected in battle. The elementary practice for the testing of gun's crews and pointers is held at a short range with a small target, just large enough to catch exactly aimed shots. This form of firing is primarily a competition between gun crews and pointers, and as a result of it the pointers are qualified.

When it is considered that a shell from a 12-inch gun, which leaves the piece with a velocity of 2,700 feet per second, at a battle range reaches a height of about a thousand feet, and strikes at an angle of approximately 9 degrees to the horizontal, it is not hard to understand the exactness with which the pointing and control must be accomplished in order to hit a moving target of small size. Loaded shells are not generally employed at target practice because of their expense. Cheaper projectiles of inferior metal, without bursting charges, are utilized for this purpose.

One of the numerous difficulties in obtaining skill in gunnery is that firing with smokeless powder causes erosion or a wearing away of the inner surface of the bore. This is most serious in the larger guns and necessitates the relining of these pieces from time to time, a procedure which costs about $10,000 and takes some months to complete. It has been found that the amount of this erosion, which like the muzzle velocity of the projectile, is a function of the weight of the powder used, and the consequent pressure, can be reduced by using smaller charges. For this reason reduced charges are generally employed at target practice in order to lengthen the life of the larger guns.

Having briefly outlined the recent development of gunnery and target practice, we will next take up the methods of training which are now employed and which have produced the results above described.

The members of the crew of United States naval vessels, as a class, are not equaled in intelligence by those of any other navy in the world. Young men are taken from every part of the country, provided they come up to the severe requirements for enlistment, and they are afforded the best of opportunities for advancement. A man with an honorable discharge from the Navy, if he sees fit to leave at the expiration of his term of service, has no trouble in obtaining a responsible position. A man who remains in the Navy, and attends to his duties, is sure of a promotion that compares very favorably with any that he may expect outside the service. Of course, he must put up with ship life and the restraints of discipline.

An important consideration in the promotion of efficiency has been the feature of competition. Gun crews on board ship are trained as carefully as any first-rate athletic team. Every detail and movement of the individual is carefully studied with the idea of eliminating interferences, and of producing team work which will develop a maximum of rapidity and accuracy of fire from each unit composing the battery.

Loaders at other than turret guns are exercised at specially designed machines, where all the operations of loading may be performed without the excessive wearing of the mechanism that would be the case if actual guns were used for the purpose.

The gun pointers hold the positions of greatest importance. These men are selected because of their peculiar fitness for this work, which requires good eyesight, coolness, and nerve. In choosing candidates for the important duties of gun pointer, no qualities but these are taken into consideration. Pointers are carefully instructed in the manipulation of the piece and the duties of their station, and thoroughly drilled before their abilities are tested at elementary practice.

Pointers are divided into classes, and are given a gratuity each month in addition to their regular pay as shown in the following table:

Class	Duty	Additional monthly pay	
		1st class	2nd class
Heavy gun pointer	Pointers of guns of a caliber of 8-inch or above	$10	$6
Intermediate	Pointers of guns from 4 to 8-inch caliber, inclusive	8	4
Secondary	Pointers of 1 pounder to 3-inch caliber	4	2

The torpedo has steadily come to the front as a weapon. There are now torpedoes capable of running 11,000 yards at a speed of about 28 knots, and carrying over 200 pounds of high explosive. Torpedoes are carried on all classes of vessels, but are essentially the weapons of the destroyer, fast torpedo boat, and submarine. They are discharged from tubes either above or below the waterline. These projectiles are kept on straight, predetermined courses by means of gyroscopes. They are regulated in depth by means of a hydrostatic piston and pendulum, and are driven by engines operated by compressed air.

First Division maneuvering, as seen [illegible] bridge of the "North Dakota."

The "war head" of a torpedo, containing the high explosive, and the nose for detonating the latter, are not used in exercise. This head is replaced by one filled with water which collapses on impact, without serious damage to the torpedo, and which may without injury be fired against the hull of a ship.

The torpedo men are usually given a special course of training and instruction at the torpedo school in Newport, where they are taught to care for the delicate mechanism of the torpedo and to make the adjustments necessary for successful running. Successful gun and torpedo crews are distinguished by a small block letter "E," which members thereof are authorized to wear on the sleeve for one year after the completion of the practice for which it has been awarded. Money prizes are also given to each man of gun and torpedo crews making the highest scores at target practice. A first prize amounts to $20, a second prize to $10, and a third prize to $5.

It is considered of importance that officers and men should have skill and knowledge of all the weapons which they may at any time be called upon to use, and special attention is given to the use of small arms in the Navy. When the record of an enlisted man shows him to be a sharpshooter or an expert with a small arm, he becomes marked at once as a trained man as well as probably one with nerve and sense of responsibility.

The large and well-equipped target range at Guantanamo, Cuba, is an excellent place for small arms work and for instruction and experience in landing operations. Each year vessels of the Atlantic fleet are required to land their men, and to conduct them through the small arms courses, and at the same time to exercise them in camping and in shore drills.

Cash prizes and medals are given for excellence with small arms and to the ship of the Atlantic, Pacific, and Asiatic fleets making the best performance for the year with these weapons is awarded the silver trophy for "small arms," which is held by that vessel for one year.

The combination of the scores of individual gun and torpedo crews at target practice is worked out, and the final standing of ships for the different practices are determined by the Department. At the end of the year the final combined scores for all forms of firing are determined for the different classes of vessels, and the trophies in gunnery are awarded.

These trophies are handsome bronze plaques on which are engraved the names of winning vessels. A trophy is carried by the leader of her class for one year. Letters of commendation are addressed to the officers deemed deserving of these at the close of the annual competition.

A competition is also conducted in engineering in the Navy, which has done much to produce economy in the expenditure of fuel, oils, etc., to promote efficiency, and to improve design.

Trophies similar to those awarded for gunnery are offered for excellence in this, and the members of the engineering department of the trophy winner are permitted to wear red "E's" on the sleeves of their uniforms similar to those authorized as a result of target practice to successful gun and torpedo crews.

Finally, the standings in the competition in engineering and in gunnery for each year are combined. Engineering is given a weight of 40 and gunnery of 60, and the multiples for what is termed "Battle Efficiency" are then determined for the different classes of vessels.

The leading vessel in "Battle Efficiency" of each of the different classes is awarded the right to fly the much prized pennant of red with a black ball for one year as a symbol of proficiency. It has been customary for the President to address a congratulatory letter to the captain of the battleship securing this prize, and for the Secretary of the Navy to similarly recognize the leading destroyer and submarine.

The above outlines the methods in vogue for the encouragement of competition between ships. The success of a vessel, in these competitions, is almost in every case directly measured by the spirit of the crew, and the pride and interest taken by them in the work of their ship, and this depends, almost entirely, on the attitude and intelligent zeal of the officers and the success with which they are able to co-ordinate and interest the men in accomplishing useful work.

The public accustomed to seeing the sailor about the streets of our seaports, seemingly idle when other men are busiest, does not always remember that this individual has been living with his work by night as well as by day for weeks and often months. Diversion and complete relaxation from his routine from time to time are necessary.

Because of the tremendous power and accuracy of modern ordnance, the effective use of their gun fire, on the part of one's opponents, in battle must be prevented. To accomplish this it is not only necessary to be able to hit at greater ranges than those at which an enemy is capable of hitting, but also to be able to make more hits than he under the difficult conditions imposed by a rough sea or bad weather, or with a rapidly changing range.

Eliminating the Flicker From the Moving Picture

A New System of Motion Picture Projection

By Joseph B. Baker

Motion picture projection rests upon the physiological phenomenon of "persistence of visual impression," whereby a momentary glimpse of a well-illuminated object prints an image on the retina which remains about one sixteenth of a second. In the ordinary motion picture method a rapidly succeeding series of snapshots are taken. These pictures are made one after another at the rate of sixteen per second upon a narrow strip of film, which is made to travel through the motion picture camera at the rate of one foot per second. There are therefore sixteen complete pictures in every foot of film. If the camera is pointed toward a scene in which is a falling weight, and the first picture shows the weight in the middle of the view, the second picture, taken one sixteenth of a second later, will show the weight in a new position slightly below, and the third will show a still further displacement of the weight, and so on. Say the weight has moved one foot between the instant of taking the first picture and the instant of taking the second picture. These two pictures will then show the beginning and the end of that one foot of movement, and there is nothing but a gap or blank in the interval between the pictures.

A thousand feet or more of this film may be taken of any moving scene. The projection on a screen to simulate the original scene is accomplished by making a positive transparency of the film negative and running the same through a specially contrived projection lantern, which throws an enlargement of the first picture upon the screen for an instant, then cuts off this image and one sixteenth of a second later throws the second picture on the screen, and so on. Before the impression of the first image has faded from the retina of the observer, the second image is impressed. The eye, retaining its impression of the falling weight as at one point in the general view and receiving an impression of the weight as at a new point, superposed upon the still lingering first impression, takes for granted the intermediate positions of the moving object. Thus it supplies, subjectively, the continuity of movement of the object—a continuity which is really quite lacking in the series of screen pictures. The action is just the same as viewing a field of running horses through a picket fence, as one travels along outside the fence. At a given instant the eyes have a clear view of the animated scene through a space between two pickets, the next instant the view is absolutely cut off by an interposing picket, then comes a new view through another space and another cut-off; but all the time the movements of the horses are seen apparently without a break. This system has its objectionable aspects. The film must move constantly so that it may not catch fire, and the "flicker" produced by the rapidly succeeding pictures produces eye strain. In the accompanying article an ingenious method is described, whereby it is sought to overcome these defects.—**Editor.**

THE ordinary motion picture apparatus demands a good deal of what might be termed continuity-preserving effort on the part of the human eye—just as catching spoken words reproduced by a phonograph or in a telephone receiver demands a good deal of the ear, in supplying with the imagination vocal sounds which are not fully reproduced by these instruments or not reproduced at all. (The field of mechanical devices is full of such partial accomplishments eked out by the accommodating human senses.) In the present system of motion picture projection, moreover, the rapidly recurring dark intervals between successive screen images and the eyestrain by variation of illumination (the so-called "flicker") have been objectionable to the observer. In the projecting machine, also, the intermittent movement of the film, the danger of fire from the heat to which the film is subjected during the instant it is held still for the projection of each picture, and the noise of operation, have been features that demanded radical improvement. A picture is projected for about 75 per cent of the picture interval of one sixteenth of a second; in the remaining 25 per cent of this interval the image is cut off by the blade of a revolving shutter, while the next picture is being brought into the focus of the lens; then No 2 picture is projected. Part of the time a single, fixed image is on the screen; the rest of the time the illumination is absolutely cut off. The eye, staring at the screen, must use its faculty of persistence of impression to help fill in, so to speak, the abrupt dark interval and then suddenly receive a new shock of full illumination. The eye is bombarded with a series of impressions very sharply and definitely spaced apart by periods of absence of illumination on the screen. As in watching a prestidigitator we enjoy imagining an actual flight of the mysterious coin from the operator's palm to the table-top thirty feet away, so the eye "plays up" in the enormously more rapid and continuously exacting game of bridging the gaps of the motion picture film.

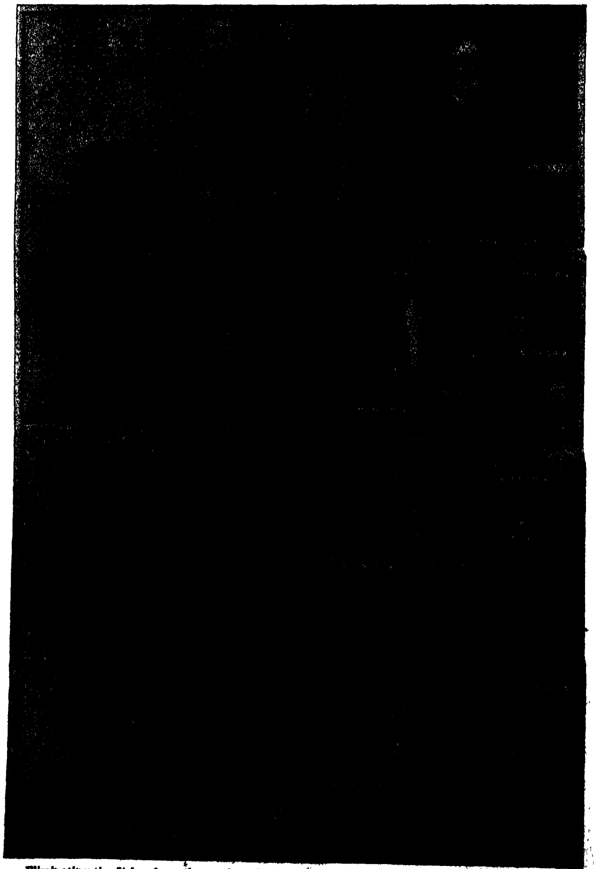
But in enduring the flicker the eye pays heavily for its self-imposed delusion. The resulting eyestrain is a disadvantage which the public puts up with, and seeks to counteract by watching the screen at a distance of at least twenty feet back within a rather narrow sector.

The fire danger may be estimated from the intense light necessary to obtain a continuous visual effect of good illumination in the screen picture notwithstanding the very large ratio of enlargement (about 1 to 97,000) and notwithstanding the intermittency of the actual illumination. It may be said that the film is always just on the verge of igniting. Hence the strict fire laws governing motion picture exhibitions.

A new machine called the vanoscope overcomes these imperfections in an apparatus giving a continuous visual impression from a steadily moving film. Its "moving picture" is not made up of abruptly succeeding fixed images separated by dark intervals, but of images which genuinely dissolve into one another without any interruption of the full illumination upon the screen. While the apparatus will project any standard film, the successive pictures may be taken at very much longer intervals if desired, that is, fewer per second than the limit of sixteen per second required for the present system, and they may be reproduced at the same slow rate on the screen—a feature invaluable for educational and motion study work. In fact, the normal speed is 8 per second, which gives very great reduction in the length of film. It is possible to put a "1,000-foot play" on 800 feet of film. "Travel ghost" is eliminated. The pictures are projected without being abruptly cut off by a shutter, but by actually "dissolving," one image decreasing in intensity of illumination simultaneously with the increase in illumination of the next succeeding image. As at an ordinary lantern-slide exhibition, where a view of Fujiyama, for example, melts into a view of a crowded street in Nagasaki, the eye has only to relinquish the outlines of one picture and take up the outlines of the next, with comparatively little physiological effort.

To obtain this result a new mechanical movement of four mirrors, being the four right-angle segments of a circle, which deliver the film image to the projecting lens, is employed. Each segment of this four-part reflector has conveyed to it a movement such as would be given by rotating it on an imaginary axis and simultaneously rocking it for-

(Concluded on page [illegible].)



Eliminating the flicker from the moving picture. A series of pictures that show how it is done.

Where and How Radium is Obtained

The American Supply of the Most Precious Substance in the World

By John L. Cochrane

THE wonderful radium which is exciting so much comment these days because of its reported curative properties, especially in the instance of superficial cancer, is obtained from the minerals carnotite, pitchblende and also autunite. The popular belief has been, until recently, that the chief source of radium is the mineral pitchblende, especially that obtained from the mines now under the control of the Austrian government, at Joachimenthal, Bohemia. Outside of the ore in Austria, the only pitchblende deposits of any size are those in Gilpin County, Colorado, from which some thirty tons, more or less, have been procured since the mineral became valuable as a source of radium. The most important source of radium is the carnotite ore and the greatest known field of this ore is in the Paradox Valley of Colorado and Utah. There is a little carnotite in South Australia and in Russian Turkestan, but the supply of carnotite in the Paradox Valley is so great as to lead scientists to make the statement that the United States practically has a monopoly of the radium-bearing ores of the entire world. The autunite deposits of Portugal and South Australia are unimportant.

In order to aid prospectors in their search for radium-bearing ores and to enlighten persons all over the country who had a faint suspicion that their rear yards contained the precious substance, the National Bureau of Mines but recently issued the following:

"Radium is found with uranium minerals only. Wherever uranium exists, radium is also found in the mineral; and where there is no uranium, radium has never been found. Uranium and therefore radium are found in this country in carnotite and its associated minerals, and in pitchblende. Carnotite is a lemon-yellow mineral, usually found in pockets of sandstone deposits. The mineral may be in the form of light yellow specks disseminated through the sandstone, or as yellow incrustations in the cracks of the sandstone; or may be more or less massive, associated with blue, black, or brown vanadium ores.

"Pitchblende is a hard, blue-black ore that looks something like magnetite, but is heavier. It is found in pockets and veins in igneous rocks. This mineral is not nearly as widely distributed as carnotite. Occasionally it is found associated with an orange mineral called gummite."

Although, until recently, the manufacture of radium from carnotite has been carried on almost wholly in France and Germany, the American ores having been shipped in great quantities, there appears no good reason why our American carnotite should not be treated at home. Carnotite is much more easily treated than pitchblende and the essential features of methods for its chemical treatment are well known, although much of the mechanical detail of operation has been kept secret. As the mechanical requirements, however, are those which any well grounded chemical engineer should be able to solve, there seems to be no reason why any of our carnotite ores should be shipped abroad, even at two or three times the present market price of the material. As regards the principles involved, the methods have advanced little beyond the original method published by Debierne.

How Radium is Reduced.

The manufacture of radium from carnotite is a long, tedious, laborious chemical process, complicated in the extreme by the great difficulties encountered in separating the various foreign elements in the carnotite from the radium. The process has been likened to the method used in the purification of the table salt in every day use. The salt is placed in solution and the impurities driven off by crystallisation. This, however, is a child's work in comparison to the extraction of radium from carnotite. The carnotite is placed in solution, and step by step the various other elements are reduced in quantity through the process of crystallisation, each step leaving the radium freer from its associated impurities. The methods for extracting the radium from carnotite are best described by an eminent chemist in the following words:

"The most important operations in the working up of radium-containing materials are the solution of the materials, consisting usually of insoluble sulphates, and the separation of the halogen salts of the alkaline earth group in a pure state, followed by their fractional crystallisation. The first operation is usually effected by vigorous boiling with sodium carbonate solution, filtering and washing free from sulphate. This is the well known reaction studied dynamically by Guldberg and Waage, whereby an equilibrium is attained between the two pairs of soluble and insoluble sulphates and carbonates. Naturally the greater the excess of sodium carbonate the larger the proportion of insoluble sulphate converted into insoluble carbonate. In this operation it is advisable not to wash at once with water, but with sodium carbonate solution until most of the sulphates are removed, as thereby the reconversion of the carbonates back into insoluble sulphates is largely prevented. In dealing with crude materials—for example, the radium-containing residues from pitchblende—it is often advantageous to precede this operation by a similar one, using sodium hydrate solution containing a little carbonate, which dissolves part of the lead and silica present. The carbonates, washed free from sulphates, are treated with pure hydrochloric acid, which dissolves the alkaline earths, including radium. From the solution the latter may be precipitated as sulphates by sulphuric acid and reconverted back into carbonates as before, or sometimes more conveniently they may be precipitated directly as chlorides by saturating the solution with hydrogen chloride. This is a very elegant method of great utility in the laboratory, for the most probable impurities, chlorides of lead, iron, calcium, etc., remain in solution and only the barium and radium chloride are precipitated practically in the pure state, ready for fractionation."

Radium-bearing carnotite bags ready for shipment.

Nearly all American carnotite is sent to Europe for treatment. Now that we are beginning to evince some interest in our radium ores, perhaps we may soon treat carnotite ourselves.

From left to right—Dr. Karl Kithil, Dr. Richard B. Moore, chemists in the Bureau of Mines Laboratory at Denver, Colorado. Dr. Moore is in charge of the work of extracting radium from carnotite.

Miner showing carnotite in place, Paradox Valley, Colorado.

The manufacture of radium from carnotite is a long, tedious, laborious chemical process, complicated in the extreme by great difficulties in separating the radium from many foreign elements.

The National Bureau of Mines, at the suggestion of Dr. Joseph A. Holmes, established a laboratory at Denver, Col., two years ago for an investigation of the rare ores and immediately plunged into a method for the extraction of radium from the carnotite. Dr. Richard B. Moore and Karl Kithil, in charge of the laboratory, as the result of their work, declare that the simplest way to extract uranium, vanadium and radium from carnotite is to treat the ore or concentrate directly with boiling concentrated nitric or muriatic acid. Even the vanadium and silica combinations can be decomposed by boiling with these acids for an hour, nitric acid giving the better results. They found that carnotite itself is soluble in cold dilute hydrochloric or nitric acid. The practicability of such a process, they say, depends upon its cost and the possibility of readily recovering the radium.

At the time the Bureau of Mines began its labors in Denver, no radium was being manufactured in the United States. The carnotite ores were being shipped to Europe at an alarming rate and at a price in no measure commensurate with their value. The ores are still being shipped, but all of it is not going out of the country. At least two American concerns are making radium and one has already placed some on the market, but it is understood that the output of this concern, for some time to come, will go to Europe. That the extraction of radium is apparently a very profitable business is seen in the assertion of the chemists of the Bureau of Mines. Messrs. Moore and Kithil say that while the cost varies in different places, being governed by the cost of labor, chemicals, freight, etc., $20 per milligramme is probably a maximum cost in Europe for extracting radium from carnotite ores. When it is considered that radium is selling for $120 a milligramme the wide margin of profit can easily be seen.

An important development as a result of the investigations of the Bureau of Mines has been the establishment of the National Radium Institute, with Dr. Howard A. Kelly of Johns Hopkins Hospital, Baltimore, as president, and James Douglas of New York as one of the incorporators. This institute has obtained the right to mine the carnotite ores on twenty-seven different claims in the Paradox Valley for a period of three years. A mill for the concentration of the ores and the extraction of radium is now being built in Denver. The institute has been formed for the special purpose of procuring enough radium to conduct extensive experiments in radium therapy with special reference to curing cancer. The extraction of the radium from the carnotite ores will be made by the Bureau of Mines for the Institute.

Less Than Two Grammes of Radium in United States.

There are certain facts to be borne in mind in regard to the radium situation, and the first and most important is that there are less than two grammes of radium in the entire United States at the present time. In the entire world, the supply is estimated at 30 grammes, and the great bulk of this came from American ores. It is stated on authority that not more than two American physicians have enough radium to use in the treatment of cancer. One of these is Dr. Kelly, the famous Baltimore surgeon, and he has more than half the entire supply in the entire country. He declares that instead of one gramme, he should have ten grammes.

A New Governor for Motor Vehicle Control

An automatic governor is necessary for power vehicles not only on the score of prolonging the life of the motor, but also on the score of fuel economy.

But the automatic governors employed to-day do not assist the driver in the operation of the vehicle. They are merely speed limiters, and as such they may be divided into two classes, namely: governors which limit the motor speed directly, through curtailing the gas flow, and indirectly the vehicle speed; and governors which limit the vehicle speed directly through its influence on the motor, and indirectly the motor speed, through curtailing the gas supply, or by grounding the ignition The non-ignition method, owing to the many and serious objections to it, can have only a very limited application, and will not be considered here

It is conceded generally that these governors have serious limitations, yet it has been the policy of many designers to provide their vehicles with them on the assumption that the disadvantages resulting from omitting them would be far more serious than those from using them.

The requirements of an efficient motor vehicle governor are that it accomplish at least five things; first, it should provide a positive control of the maximum speed of the motor, at all times, whether running idle or under load; second, it should permit of different maximum motor speeds for the different gears, and it should confine those speeds, so far as possible, considering the power requirements for the different gears, to within that zone of motor speeds corresponding to the highest motor efficiency; third, it should do this through a mechanism capable of simple and accurate adjustment whereby the maximum speed of the motor, and the maximum speed of the vehicle, may be raised or lowered at will to suit the varying conditions of service for which the vehicle has been designed, or provided; fourth, it should provide a valve mechanism, free from fluttering tendencies, which will effectively and economically feed the gas mixture to the motor only in such amounts as may be needed to develop and to maintain the desired power, and no more; and, fifth, all of these functions should be included in a mechanism of such simple design and substantial construction as to be fool-proof and tamper-proof, and capable of being locked, or sealed

The need of such a governor has been keenly felt in the vehicle industry, and yet no progress seems to have been made in evolving such a design until the recent advent of what is known as the duplex governor, which is now undergoing some severe trials by several of the large commercial vehicle manufacturers, and the reports concerning which are said to be very satisfactory

This governor was designed on the principle of a dual actuating influence. This double influence consists of a motor influence, as to its speed, which is imparted to the governor, and a vehicle influence, as to its speed, which is also imparted to the governor. The motor speed may be conveyed from the timing gears, magneto shaft, etc., and the vehicle speed from the propellor-shaft, or jack-shaft. The conveying speed means consists of a one quarter inch, sixteen strand, steel cable revolving in a hard fiber, or metallic casing The centrifugal member, valve member, and adjusting member are all consolidated into a single unit within an inclosing shell which is interposed between the carbureter and the intake manifold of the motor, in such a manner that the entire gas supply must pass through the valve.

On each side of the valve chamber provision is made for the insertion of a speed terminal, one conveying to the governor a proportionate vehicle speed, and the other conveying a proportionate motor speed Within the governor there are two automatically acting one-way clutches, the floating members of which consist of gears in mesh with a third gear mounted on the centrifugal governor spindle. These clutches are so designed as to impart to the centrifugal member that of the two speeds which is the higher. With the motor running idle the motor speed will actuate the governor, and the motor is always under governor control. When the vehicle is in motion, and is being propelled by the motor on high gears, the speed imparted to the governor by the vehicle will be the higher speed and will govern the motor, whereas on low gears the motor speed will be the higher and will govern the motor.

The governing valve employed is a grid valve of special construction and is said to be entirely new in the industry. It consists of a fixed part set into the upper part of the valve chamber and provided with elongated slots having flaring walls from its under surface outward. Below this fixed part a movable part, provided with a corresponding series of slots having flaring walls from its upper surface downward, has an arc movement along the line of the minor axes of the slots, or across them, and is supported by means of a substantial bearing The maximum travel of this movable part is less than one eighth of an inch; yet that small travel effects all degrees of aperture between full open and full closed valve When the openings of the rigid part coincide with the openings of the movable part the valve is open, and when the bars of the rigid part cover the openings of the movable part, and *vice versa*, the valve is closed. The two parts of the valve have a ground fit. The movable part is held in open position by means of spring pressure, and its possible motion, in both directions, is limited by suitable adjusting screws

A new type of gasoline engine governor.

How the governor is applied to an automobile engine.

The influence of the centrifugal member, as a result of the speeds imparted to it, is to develop a pressure sufficient to overcome the spring pressure tending to hold the valve in its open position, and to close the valve. As soon as this pressure is removed the movable valve part is released, and returns to its full open position. The adjustment factor is constant for all speeds. The increase of the centrifugal pressure, as the square of the speed increases, is balanced by a spring pressure tending to return the centrifugal weights to their negative position, plus the spring pressure of the movable valve part. The working combination between the centrifugal member and movable valve part is influenced by the adjusting screw. The locking yoke may be removed and the hand-wheel turned to the right, in which case the possible vehicle and motor speeds are reduced, and if turned to the left, they are increased. This results from the lengthening or shortening of the valve stem, and thus increasing or decreasing the required travel of a floating collar, carried by the centrifugal member, to influence the position of the valve.

It is claimed that the construction of the valve and its actuating influence are such as to free it from all vibration; its movable part is balanced, and its center of gravity lies within its center of support. The openings of the valve parts, when superimposed, are so designed as to constitute elongated venturi with a view to wire-pulling all of the gas passing through the valve, and for the further purpose, through the flare of the walls of the openings, to establish slight cross currents in the gas flow to promote the better commingling of its ingredients.

The centrifugal member revolves in a chamber entirely separated from the gas chamber, and in an oil bath. This chamber contains all of the moving parts of the unit, except the valve and yoke parts in the valve chamber, which have a maximum movement of less than one eighth of an inch. A screw cap is provided to cover the adjusting means, which may be locked or sealed.

Among other vehicles the governor was applied to a five-ton truck. Before the application a careful service run of the truck was made across country with a gross load of 10,000 pounds, and without a governor. The motor control was by hand and pedal with a very careful effort made to maintain a speed of 9.5 miles per hour, and not to exceed it A record was kept of the other factors of the performance. The governor was applied and a corresponding, and in every way similar, run was made over the same roads and for the same distance with the result that it was done in 21 per cent less time, with an average speed of 8.85 miles per hour, as against an average of 7.5 miles per hour of the previous run; with 20 per cent less gasoline; with an average reduction of 10 per cent of radiator temperature; and 5 per cent less piston travel. Of the hills on which it was necessary to drop below third gear without the governor, 70 per cent were made on third gear, proving thereby that the automatic control was to that extent more efficient than the personal control. This resulted largely from the fact that the best of drivers will misjudge their grade and road resistances and will not work for any length of time at a high efficiency, whereas with the automatic control the vehicle is kept up to its best performance, and when it reaches a grade it has its maximum momentum, the motor is turning over at its maximum speed for that gear, the motor is being given just as much gas as it will take to maintain that speed, and without either starving or loading-up tendencies.

When the governor was applied to a pleasure vehicle (a six-cylinder roadster), in which the maximum vehicle speed is limited to thirty miles per hour and the maximum motor speed to 1,000 revolutions per minute, it was demonstrated that the maximum vehicle speed can be maintained on fourth and third gears, on which gears the vehicle controls the motor, and on the other gears a reduced, but relatively high speed can be maintained with almost 100 per cent increase of power

(Concluded on page 15[illegible].)

DELCO

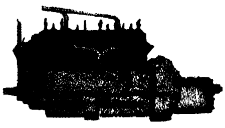
ELECTRIC CRANKING LIGHTING IGNITION

Three Epoch Making Steps in Automobile Development

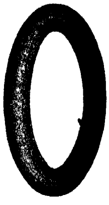
The automobile of today is an almost perfected machine.

Powerful, speedy, splendid in its ability to do things—yet under such complete control that it is as easy to operate as an electric carriage.

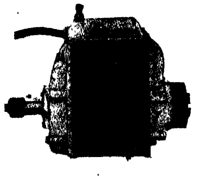
There have been three epoch making steps in the development of this remarkable machine—



THE GASOLENE MOTOR—We might have had motor cars without the gasolene engine. Steam or electricity might have served as the motive power—but they would not have been the splendid high powered, flexible machines that have so revolutionized our ideas of time and distance. The gasolene engine is fundamental to the automobile as we know it today.



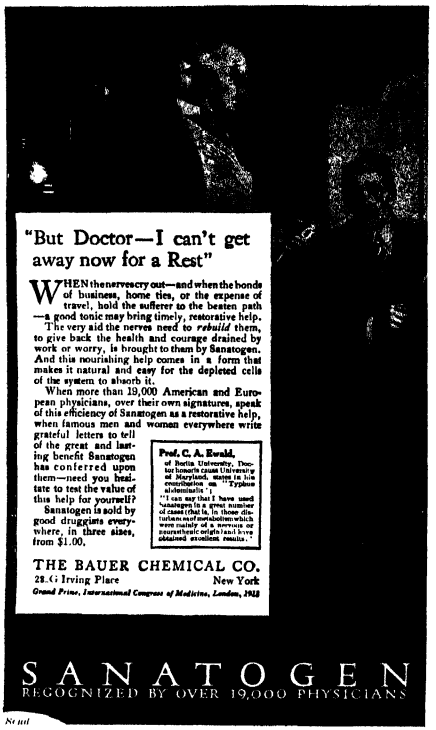
THE PNEUMATIC TIRE—But even with the gasolene engine simplified and perfected to its highest efficiency its usefulness would have been sadly curtailed had not the pneumatic tire come to make its full development possible. The pneumatic tire, too, is fundamental to the twentieth century automobile.



THE DELCO SYSTEM—The Delco System has been the refining influence in the development of the gasolene car. It has eliminated the crudities of the crank and of hand lighted lamps. It has provided an ignition that is thoroughly dependable under all sorts of operating conditions. It has furnished an always available auxiliary power that removes the danger of accident when the engine stalls unexpectedly in a tight place. It has immeasurably broadened the scope of the automobile by making it so easy and safe to operate that almost any one can readily master it.

The Delco System is the pioneer in the Electric cranking and lighting field—and today two-thirds of all the electrically cranked cars in existence are Delco equipped. Verify this last statement for yourself—count the electrically equipped cars you see on the street.

The Dayton Engineering Laboratories Company, Dayton, Ohio



"But Doctor—I can't get away now for a Rest"

WHEN the nerves cry out—and when the bonds of business, home ties, or the expense of travel, hold the sufferer to the beaten path—a good tonic may bring timely, restorative help.

The very aid the nerves need to *rebuild* them, to give back the health and courage drained by work or worry, is brought to them by Sanatogen. And this nourishing help comes in a form that makes it natural and easy for the depleted cells of the system to absorb it.

When more than 19,000 American and European physicians, over their own signatures, speak of this efficiency of Sanatogen as a restorative help, when famous men and women everywhere write grateful letters to tell of the great and lasting benefit Sanatogen has conferred upon them—need you hesitate to test the value of this help for yourself?

Sanatogen is sold by good druggists everywhere, in three sizes, from $1.00.

Prof. C. A. Ewald, of Berlin University, Doctor honoris causa University of Maryland, states in his contribution on "Typhus abdominalis":
"I can say that I have used Sanatogen in a great number of cases (that is, in those disturbances of metabolism which were mainly of a nervous or neurasthenic origin) and have obtained excellent results."

The Hope-Jones Orchestra

(Concluded from page 137)

There is also an armature disk valve *M* made of soft Swedish charcoal iron that rests normally upon a hollowed metal cap *N*, which is perforated by two crescent shaped openings. Directly above this disk there is an electro magnet *Z* fixed rigidly into a metal plate.

Under normal conditions the weight of the armature disk valve causes it to remain seated upon the raised faces of the cap seat *N* in such a manner that the compressed air contained in the wind chest *B* passes between the poles of the electro magnet, fills the cavity in the cap seat *N* and then passes, by means of the passage *P*, into the primary pneumatic bellows or motor *Q*. When the musician depresses one of the keys on his keyboard an electric contact is established and a current at about 10 volts pressure flows through the flexible cable connecting his keyboard with the instrument proper, and by energizing the electro magnet, raises the armature disk valve *M* so that no more compressed air can flow from the wind chest *B* into the passage *P*. Hence, the compressed air already in the primary bellows *Q* escapes to the atmosphere through the passage *P*. This results in the collapse of the pneumatic motor *E* and the consequent lifting of the valve spindle *H* (as described before), producing sound in the organ pipe *J*

In the above mechanism the areas of the various channels, valves, pneumatic motors, etc, bear a carefully calculated relation one to the other, with the result that a seemingly incredible speed of action is obtained Tests by means of revolving toothed wheels have shown that an organ pipe may be made to give its full tone and assume silence no less than 300 times per second

The initial pressure admitted to the pipe for a small fraction of a second is considerably greater than the pressure of the compressed air in the chest *B*, thus giving what the inventor describes as a "pneumatic blow" to start the speech of his pipes. This wonderfully rapid action has entirely altered the organ as a musical instrument. It places the musician in such intimate touch with his pipes that he is, within certain bounds, able to produce accents and many other variations. Every pipe and other tone-producer in the instrument is equipped with an electro-pneumatic lever described above, and under its control.

The keys which the musician operates are made very short and as light as is practicable, with the object of eliminating inertia. Upon pressing the key, contact is made between a bar of silver attached to the key and a number of very fine silver wires secured to the key frame. Through the contact thus made, the electric current passes to an electro-pneumatic relay which closes from 10 to 30 similar silver contacts, according to the size of the instrument. The current then passes through a multiple switch to the electro-pneumatic lever controlling its appropriate pipe.

The multiple switch last referred to can be closed or opened by means of one of the stop keys arranged in a semi-circle just below the music desk.

Each one of the key boards upon which the musician plays, including the large one operated by his feet, is fitted with a double touch The key descends in the ordinary manner to its usual depth; it then meets a small lever held firmly in place by a spring already under tension. If the musician presses one of his keys with greatly increased force, this small lever and spring will be overcome and the key will fall another sixteenth of an inch, thereby giving an additional second touch contact to cause some other pipe or tone producer to give a different quality of tone.

All the keys are also fitted with a pizzicato touch which can be switched on and off by the musician. When brought into operation the current, supplied through one of the silver contacts below the keys, flows for an instant to the electro-pneumatic lever controlling an additional set of pipes or other tone producers.

Smoke Five With Me

Here is a private cigar, made up specially for me, banded with my monogram.

It is made from a special Havana leaf, selected in Cuba by a man who resides there, a rare connoisseur on tobacco.

This is the sweetest smoke I ever discovered, though I've smoked for 40 years. I have never found in a ready-made cigar such a mild and exquisite aroma. So I have this leaf made up for me in the size and shape of this picture.

This cigar is rather a hobby of mine. And I am glad to supply it to other men with a taste for dainty Havanas. But I seek only men who want something exceptional—rare, delightful smokes.

I send the cigars by Parcel Post, so supplies are very convenient. The price is $5 per hundred—$2.60 for 50—charges paid. That price is not far from my cost.

Five Cigars Free

If you will send me 10 cents—just to show your sincerity—I will mail you these cigars. Smoke five with me—convince yourself. The price is $5 per hundred, $2.60 for 50—all charges prepaid. Use your letter-head, please—stating your position—or your business card and write now for these cigars.

MOORE'S THE ORIGINAL NON-LEAKABLE FOUNTAIN PEN

TO be perfectly satisfactory a Fountain Pen must write at the first stroke and continue to write freely and evenly. It must have a large ink capacity; it must fill easily and most important of all, it must be absolutely non-leakable no matter how it is carried.

In other words, it must be a Moore's, the first fountain pen to which the word non-leakable could be accurately applied and today the one pen that you can thoroughly trust to be true to its name.

There's a Moore to suit every hand. For sale by dealers everywhere.

Every part of every Moore's is unconditionally guaranteed.

[illegible] APPROVAL [illegible]

But as soon as the first tone commences again the second is immediately cut off. When a certain number of pipes are responding normally to the keys and certain others are responding through the pizzicato touch, the attack or spit of certain instruments of the orchestra is very closely imitated. Other novel and charming musical effects may also be produced.

To what greater degree the instrument may be still further improved can hardly be predicted, for now almost anything seems possible. At present it is possible to obtain the effects of as many as 150 instruments in all their varying tones, and further, these effects can be only such as are reproduced by the very finest artists. It will be of great interest to the scientific as well as the musical world to watch the further work of Mr. Hope-Jones.

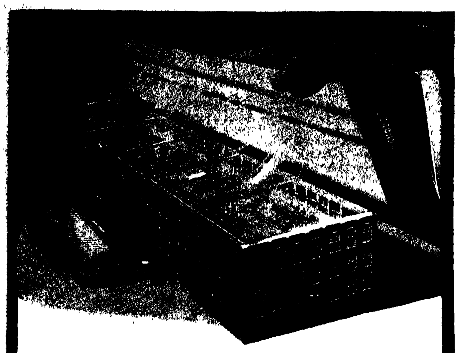
Eliminating the Flicker from the Moving Picture

(*Concluded from page 148.*)

ward at one half the angular velocity at which the film travels. The annexed drawings of a vanoscope apparatus of earlier design, equipped with two half-circle instead of four quarter-circle mirrors, show the succession of events by perspective and side views. In the perspective view of Fig. 1 the picture *A* is being projected by mirror *A* through the lens to the screens; the side view shows the position of the mirrors (exaggerated for clearness) when picture *A* is being projected solely by mirror *A*. Fig. 2 shows the conditions after the film has been moved forward a short distance, and mirror *A* has been rotated to a point where it is about to pass out of the field of light; and mirror *A* has also been rocked forward, as shown in the side view, at one half the angular velocity of the film, so that the picture as projected has been continued as a stationary image on the screen. Fig. 3 shows picture *A* after the film has moved still farther forward and mirror *A* has been rotated to a position partly out of the light field. The whole of the picture is still being projected upon the screen by this mirror, but the image is only partially as *brilliant* as it was when the mirror was fully exposed to the light; and picture *B* is now also being projected, with partial illumination, by mirror *B*, and is gradually increasing in brilliancy in proportion as the illumination from mirror *A* is decreasing. The actual image on the screen is therefore now made up of both picture *A* and picture *B*. It is in fact a composite of them both, the pair making together 100 per cent of illumination in a dissolving picture. As one mirror segment moves out of the field the lessened illumination is compensated for by the increased illumination of the next mirror segment moving into the field.

Whereas in the ordinary motion picture apparatus the illusion of continuity is a physiological effect, in the new system this illusion is largely produced as an optical effect in the apparatus. Persistence of visual impression is not so severely taxed, and in the co-operation of machine and eye the machine does a much greater part of the work than it does in the old system. The picture appears to "stand out" from the screen, owing to the heightening of verisimilitude by the presence of two dissolving images.

Fire danger is almost eliminated, because for given average screen illumination the amount of light (and heat) to which the film is subjected is not as intense as in the present system. In ordinary projecting the film is always moving continuously, not intermittently, so that the heat that does impinge on the celluloid strip does not have time to raise any point to anywhere near the igniting temperature. The lessened heat allows the feed of the moving film to be varied at will, and allows the film to be stopped at any desired point, as in the analysis of complex manual or mechanical motions or in nature study. The absence of sudden start and stop of the film eliminates the need of looping the film, renders the machine noiseless and free from the tremor which often makes the screen image indistinct, and saves the surface of the film from



Put sunshine on your ceiling

Buy it by the barrel and fill your factory with it. It will give you 19 to 36% more light than you had before. It will make a difference in your lighting bills and sanitary conditions which you can figure up in good dollars. Paint your ceilings and walls with

RICE'S MILL WHITE

The only oil paint (without varnish) giving a glossy, tile-like finish

It will be like sunshine on your ceiling. It will reflect every ray of your natural or artificial light down on to your machinery and into the dark corners of your plant. It will make every square inch of your floor space available for fine work and increase the efficiency of your employees.

The Sanitary Paint

Rice's Mill White contains no lead or other poisonous substance. Its tile-like surface will not collect dirt, germs and odors, or absorb light like a flat paint. It will not scale and require frequent renewals like a cold-water paint. It will not "alligator" or crack under the jar of machinery like a varnish paint.

Rice's Mill White flows easily and evenly under a 4" brush. Its heavy body makes two coats equal three of lead and oil. *It stays white longer than any other gloss paint.*

The Original Mill White

Rice's Mill White, the original Mill White paint, made a trade name of the words "Mill White." None of its many imitations has its elastic, permanent qualities. *No other paint manufacturer can use the Rice process.*

Rice's Mill White has stood the test of ten years as an interior factory paint unequalled for illuminating power, sanitary qualities and low ultimate cost.

RICE'S GRANOLITH

A tough and elastic permanent finish for concrete walls. Becomes a part of the cement to which it is applied. One coat sufficient, unless a gloss is desired. Makes the best possible primer on inside concrete and brick for a second coat of Rice's Mill White, giving a tile-like enamel finish at no more expense than lead and oil paint.

For Concrete Surfaces

Rice's Mill White is sold direct from our factory in barrels containing sufficient paint to cover 20,000 square feet, one coat. If you have that area of ceiling and wall space to cover

The Independent

The Forward-Looking Weekly Magazine

For Sixty-five years The Independent has stood for the highest aims in human endeavor in every field. It is a believer in race justice, class justice, sex justice and international justice, and it ardently strives for the consummation of these beliefs. The spirit of The Independent cannot be better expressed than in the motto which the French Revolutionists made glorious as the ideal—Liberty, Equality, Fraternity. LIBERTY for all men and women to do what is for their best good, unless by so doing they restrict the liberties of others; EQUALITY of opportunity for all men and women to develop their highest possibilities and greatest usefulness; FRATERNITY, the brotherhood of man and the federation of the world.

NEW FORM AND ILLUSTRATED

The Independent now appears with a larger page, new type dress, striking pictures, new departments and new features of great distinction and a wide human appeal. The editors are concerned with live issues, with new achievements, and with the strong men and women of today and tomorrow. They are anticipating this week what you are to be thinking about next week, for THE INDEPENDENT is the Forward-Looking Weekly Journal of American life. We are sure you will find THE INDEPENDENT in its new form "good company."

Governor for Motor Vehicles

(Concluded from page 142.)

output of the motor above its possible output on high gear.

It is claimed by the inventor, as the result of actual practice both on the pleasure car and on heavy vehicles, that the maximum variation in speed, with throttle wide open, both on climbing and descending normal grades, within the power and compression limits of their respective motors, will fall within a plus or minus five per cent. Where the vehicle speed is low, as in the case of a commercial vehicle, it is recommended that the car be speeded to its desired maximum and then run on full throttle under governor control. With pleasure vehicles on open highways this plan is also feasible. It makes the driving of the car simpler and frees the driver from a great deal of nervous tension and strain which is very trying in a full day's operation.

The motor is entirely freed from the evils of pedal control, no matter how great the vehicle vibration may be, and the gas is fed to the motor only when, and only in just such quantities as may be necessary to maintain the desired vehicle speed within the limitations of motor capacity, and no more. As a result of this reduction of piston travel, and the uniform feeding of the gas mixture, radiator temperatures are reduced and lubrication is simplified.

Platinum Deposits

IMPORTANT deposits of platinum have been discovered at Wenden, Westphalia, in a region previously well known for its deposits of other metals. A territory of 500 acres has been examined and the borings from nine different drill holes show the presence of from 0.9 to 1.9 troy ounces of platinum per cubic yard, which is said to be a higher content than in the Russian deposits of this valuable metal. The actual extent of the German deposits is not even vaguely known as yet, but Mr Thomas H. Norton, American consul at Chemnitz, who has made a report on this discovery, thinks that the platinum market is likely to be profoundly affected. It appears that the metal was found alloyed with silver, and therefore would have escaped detection in an ordinary ore analysis, as in this state it is dissolved by nitric acid. The consul (who is a chemical expert) suggests that the German discovery will lead to a revision of rock analysis in other parts of the world, with the possible result of platinum being found to be a much commoner metal than it is now supposed to be. The diminishing supply of platinum has long been a serious economic problem. The present annual production is about 13,250 pounds, 95 per cent of which comes from Russia. The demand far exceeds the supply, and the price has advanced since 1892 from $89 to $488 per troy pound. The unique value of platinum depends upon the fact that its coefficient of expansion is the same as that of glass and of the materials used by dentists for artificial teeth. About one-third of the world's supply is used in the electro-technical industries, and another one third in dentistry.

Beet Sugar Industry in Great Britain

THE question of establishing this industry in the British Isles has been agitated for a quarter of a century without any tangible results until recently. Under the auspices of the British Beet Sugar Council, organized in 1910, experimental crops were grown so successfully that at the end of 1911 a large company was formed, which erected a factory at Cantley, Norfolk, and contracted for the produce of 3,366 acres. In 1913, about 4,500 acres were under cultivation for the company, and the crop was about 60,000 tons. Experienced beet farm hands have been imported from Holland to aid and instruct the English laborers. The new industry is therefore now well established in Great Britain, where it bids fair to modify materially the present economic organization of the rural districts.

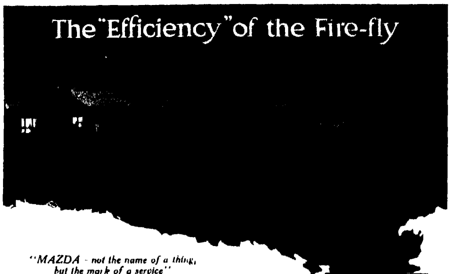
The "Efficiency" of the Fire-fly



"MAZDA — not the name of a thing, but the mark of a service"

PRIMITIVE man once used lanterns holding swarms of fireflies to guide him when he went forth at night.

Today, as Waldemar Kaempffert points out in an article on "The Light of Our Descendants" printed by the *Outlook*, the illuminating specialists of two continents are studying the firefly for a solution of one of mankind's greatest problems —artificial light

To imitate the firefly—to get a great deal of light with but little heat waste—has been the steadfast aim of technical experts in electric lighting since the study of electric light became a science

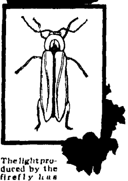
Step by step science has advanced in its search for this *economy in the fuel of life.*

That is what the much used word "efficiency" means to electric lighting science—*more light without increasing cost.*

The farthest advance in this study of lighting economy has been reached in the work of the famous group of scientists in the Research Laboratories of the General Electric Company at Schenectady These experts selected and approved the features of a lamp that gives a beautiful light—*three times as much light,* with the same amount of current, as you get from the old style carbon lamp

On the bulb of this lamp is etched the mark "MAZDA"

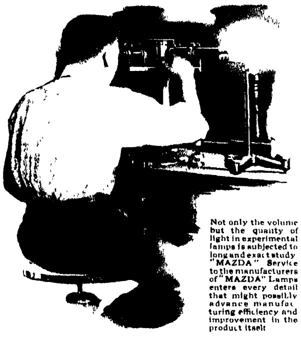
"MAZDA" is the mark of a Service It tells you of the great work that these busy men have done for the manufacturers of "MAZDA" lamps It tells you what they are doing while you are reading this article It tells you also of what they will be doing to-morrow, and next month, and next year, because it is the trade mark designation of the incessant effort "MAZDA" Service is making toward the ideal light.



The light produced by the firefly has challenged the lamp experts of two continents

On the lamps themselves the mark "MAZDA" means the selection of every "efficiency" discovery these Research Laboratories may find applicable and practical. Not content with wide investigation and experiment in these Research Laboratories, and in the active developing and manufacturing centers at Harrison and Cleveland, there is close touch also with progress that may be made by great experimental laboratories of Europe

From whatever source the new knowledge comes it is impartially considered with reference to its possible value in enabling the manufacturers to produce for you a lamp more "efficient" or adaptable The proved advances, year after year, are transmitted by this "MAZDA" Service to the General Electric Company factories and the factories of other Companies entitled to receive this Service.



Not only the volume but the quality of light in experimental lamps is subjected to long and exact study "MAZDA" Service to the manufacturers of "MAZDA" Lamps enters every detail that might possibly advance manufacturing efficiency and improvement in the product itself

The result is that when you buy a "MAZDA" lamp, to-day or at any future time, "MAZDA" Service will shine in that lamp You will know when you see that word "MAZDA" that you have the utmost result of all this indefatigable labor—the summed up success of these keenest lamp experts in the world For the lamp so marked will always mean that this Service has been applied and the manufactured product backed by this Service will always be marked "MAZDA"

GENERAL ELECTRIC COMPANY

Wood Distillation

For Manufacturing ALCOHOL and other Products of the Process

¶ Profits from refuse wood and sawdust are in reach of any one who will locate near a sawmill. The Scientific American Supplement files contain a series of valuable articles on this topic which are contained in the following numbers:

No. 1610—**A General Review of the Subject of** utilizing wood wastes, and the uses to which the wastes may be put.

No. 1684—The "steam" and "destructive" distillation processes, and **names the numerous products obtainable** from the complete operation.

No. 1661—**Distillation of soft wood,** and gives the proportions and quantities of each product obtainable, and the various processes used.

Nos. 1723 and 1724—The general subject of the utilization of wood wastes, **giving all the products** by a clear and valuable diagram showing their relations to each other, and many illustrations of apparatus.

No. 1592—**The manufacture of wood alcohol** by a German process which first converts sawdust and scraps to glucose and then to alcohol, leaving the residue of the wood with 75 per cent of its heating value, and in condition to briquette without a binder.

No. 1789—Prof Ruttau's article on the **manufacture of wood alcohol**, a very comprehensive discussion.

No. 1643—**Dry distillation of Beech and other hardwoods** comparing European and American methods, and giving the quantities of products obtained.

No. 1335—**Charcoal manufacture** in Germany, with complete recovery of by-products, their description and uses

No 1472—**"Distillation of Pine Products"** refers especially to turpentine manufacture, but covers the by-products as well, and gives information of the profitable nature of the business.

No. 1151—*Refers to acetic acid, wood spirit* and acetone from distillation of wood, and gives a good description of the necessary apparatus, and particularly of the **points to be observed in operating the plant.**

No 1736—**Production of Alcohol from Cellulose,** how wood and wood products may be used

No. 1656—Turpentine from waste wood

No 1910—The production of ethyl alcohol from waste products (sawdust, etc)

No 1915—Experiments on the hydrolysis of sawdust, sugar and alcohol from wood.

No. 1927—Recent developments in wood distillation; millions of cords of wood allowed to go to rot are capable of yielding valuable products.

No 1953—Chemical treatment of waste wood, recovering values from low-grade material.

EACH number of the Supplement costs 10 cents A set of papers containing all the articles above mentioned will be mailed for $1.70 Order from your newsdealer or from us

Joining and Cutting Metals

[by various processes is treated very fully in the Scientific American Supplement. The following issues will be found valuable to every worker of metals:]

Scientific American Supplement No. 1384—*Lead-burning*—describes an oxy-hydrogen apparatus and its use for the purpose.

Scientific American Supplement Nos. 1754, 1755 and 1756—*The Oxy-hydrogen Process* of cutting and welding metals is a series covering the important applications of this remarkable process.

Scientific American Supplement No. 1903—*Theory of the Welding of Steel and its Practical Application* This paper gives much valuable data on how welding operations should be conducted in solid and autogenous processes.

Scientific American Supplement No. 1646—*Oxy-Hydric Welding,* gives a description of processes and cost.

Scientific American Supplement No. 1775—*New Gas Fusion Process,* describes the Koeln Muesener improvement in oxy-hydric apparatus.

Scientific American Supplement No. 1680—*The Oxy-Acetylene Process,* sets forth the uses and cost of this system.

Scientific American Supplement No. 1434—*The Garuti Process of Generating Oxygen and Hydrogen,* describes an economical way of making and using these gases for welding.

Scientific American Supplement Nos. 1305, 1447, 1480 and 1873 on *"Aluminothermy"* or *"Thermit"* processes, describe and illustrate many remarkable welds, castings and other operations performed with the novel and useful series of metallic compounds, by which castings of steel and other metals and difficult welds can be easily made without forge, cupola or any sort of fireplace.

Each number of the Supplement costs 10 cents

A set of papers containing all the articles here mentioned will be mailed for $1.30

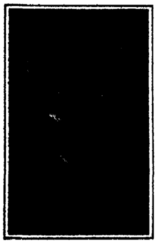
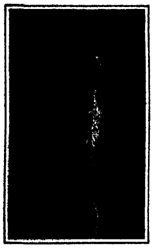
Blind visitors listening to a lecture before examining a human skeleton. The demonstration is preceded by a short lecture by a capable local specialist.



Blind men studying the form and mechanism of firearms.

"Now we know how big a lion is, but we couldn't ride a live one, could we?" Blind children making an interesting study in natural history.

Gaining impressions of a bridge and a locomotive engine, through step by step patient examination of the structural difficulties of the parts and sections.



The human skeleton. An investigation into what it is like.

"What should I see if I saw an aeroplane?" An object lesson for boys by a demonstrator who guides the hand over the features of the specimen.

Showing Museums to the Blind

By Percy Collins

MUCH has been done in all civilized countries to alleviate the hard lot of the blind, but it has been left to Mr. J. A. Charlton Deas, of Sunderland (England) to point out that the educational advantages of our museums and art galleries may be made available to the sightless members of the community. At first thought this assertion seems hard to credit. But Mr. Deas, who is librarian and museum director to the Corporation of Sunderland, has put his theories to the test, and has proved their soundness beyond all possibility of quibble. Briefly, the methods he adopts are as follows: Each demonstration is preceded by a short lecture, delivered in simple language by capable local specialists—the information given being just that interesting outline which is required by a person approaching a subject for the first time. At the close of the lecture, each blind person is taken in hand by a competent guide—one of a body of ladies and gentlemen whose co-operation had previously been secured. The business of the guides is to assist their charges to examine the series of specimens set forth for their edification. Attached to each specimen is a carefully prepared descriptive label. This is read aloud by the guide, and supplemented by any interesting knowledge of the object which he or she may possess. The hands or fingers of the blind person are then guided to the important features of the specimen. "This conscientious guiding of the blind person's hands," writes Mr. Deas, "is by no means a simple matter. When it is remembered that the voice must be used to explain each feature at the moment of touch, and that in this way only one person can be satisfactorily dealt with at a time, it will be realised that an afternoon of such work is not without its fatigue, but a fatigue that is more than recompensed by the most convincing expressions of gratitude on the part of the recipient."

In order that each blind visitor should have an opportunity to examine every object, a small card giving a list of the specimens is attached to the coat-lapel or dress, and each item is ticked off when it has been thoroughly handled. The foregoing remarks apply specially to the adult blind, who were invited to attend demonstrations on Sunday afternoons. On the Mondays following, however, the same programme was gone through for the benefit of blind children from the Council School. At these juvenile demonstrations an expert blind teacher was present, who, having already heard the lecture on the previous day, was well able to bring out the points that he knew from experience would be specially interesting to his young charges, and to explain them in a comprehensible manner. It is a noteworthy fact that many blind children are remarkably quick to assimilate instruction, and use their hands with great dexterity; a point which seems to support the views of Dr. Montessori, the new educationist, who claims that the natural way for little ones to learn about things is to touch them.

Mr. G. I. Walker (the expert blind teacher of the blind referred to above), in a letter to Mr. Deas, writes: "The satisfactory point in connection with the demonstrations is that the interest has deepened as time has passed. Discussions in the Blind Institute and elsewhere have become varied and interesting, and show that the minds of those attending have been awakened and stimulated, and made to understand that they are indeed deficient, and sadly ignorant of what is around them. This has not produced any appreciable sense of bitterness and discomfort, but has made them more sensible of the kindness and thoughtfulness that have so generously sought to bring them into contact with so many things in such pleasant fashion."

The Center of the Stars

IN a communication to the Royal Astronomical Society Mr. Turner has shown that there is a center to the stellar universe such that as we recede from it the stars become fewer in number and their velocities decrease. He shows that the division of the celestial bodies into two classes, of which the members of one class approach the center while the members of the other class recede from it, give to the terrestrial observer the appearance of their being two main directions. On this theory is explainable the relation between the velocities of the stars and the nature of their spectra, the birth of movements of rotation in opposite directions in the same nebula and the occurrences of a preponderating number of new stars in the constellation Gemini. The direction thus found for the center of the stellar universe differs but little from that deduced by Mr. Lewis from statistical observations on double stars.

Staircase Drawers

A SOMEWHAT curious idea is to put drawers in the staircase and so make use of otherwise wasted space. This may prove to be quite useful in some cases, especially in small modern houses, where even the least space needs to be made use of, owing to the lack of cupboards, which are generally absent. Drawers of this kind can be made to hold all kinds of household cleaning material, brushes, dusters and the like, as well as many objects that are not often needed. One point is that the drawers should be kept tight shut, for there is always plenty of dust on the staircase, and again, should one of them be left open, it might trip up a person who is going downstairs.

Congress on Hygiene and Demography.—The Government Printing Office, in Washington, has just completed the publication of the Transactions of the Fifteenth International Congress on Hygiene and Demography, Washington, September 23-28th, 1912. It is a voluminous document, comprising 6 volumes, some of which are in 2 parts each, so that there are 9 large books in all. This work is being distributed by the secretary general of the Congress, Dr. John S. Fulton, Maltby Building, Washington, D. C.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

President Wilson on Canal Tolls

EVERY high-minded American citizen, who puts the honor and fair name of his country above every other consideration, must have felt a heavy burden lifted from his national conscience when he learned that President Wilson favors the repeal at this session of Congress of the provision of the Panama Canal Act exempting American coastwise vessels from the payment of tolls. Mr Wilson, who had already shown himself to be one of the most just, fearless and powerful Presidents that have filled the Executive Office, has expressed his determination that the iniquitous canal toll act shall be rescinded, and in bringing his powerful hand to bear upon Congress in this matter, we believe that he will have American public opinion behind him.

Anyone with common sense and an elementary sense of honor does not have to look very far into this question to see that it involves a distinct and deliberate breach of national good faith. In the year 1901 there was a treaty concluded between the United States and Great Britain, known as the "Hay-Pauncefote Treaty," in which, in view of Great Britain's agreeing to give up certain rights which she possessed at the Isthmus of Panama, the United States agreed to operate the canal under similar working conditions as regards the ships of all nations making use of the canal. This will be readily understood if we quote article 3 of the above treaty, which reads as follows: "The United States adopts as the basis of the neutralization of such ship canal the following rule, substantially as embodied in the convention of Constantinople, signed the 28th of October, 1888, for the free navigation of the Suez Canal, that is to say: 1. The canal shall be free and open to the vessels of commerce and of war of all nations observing these rules on terms of entire equality, so that there shall be no discrimination against any such nation or its citizens or subjects, in respect of the conditions or charges of traffic or otherwise"

Now one does not have to be a lawyer to see that the passage of a law last year which exempted the ships of our coastwise traffic from paying tolls and imposed tolls on the ships of other nations was a distinct breach of faith on the part of our Government. The question is one of plain day-by-day morality; matters of moral right are universal in their application; and the code of honor is just as strict in its obligations on a powerful government like our own, as it is upon the individual citizen Nay, is it not infinitely more binding? A breach of faith on the part of one man concerns himself only; but a breach of faith on the part of our Government reflects upon every one of the one hundred millions of people who live beneath its flag.

In some of the written and spoken discussions of this canal act as expressed on the platform and even in Congress itself, there has been exhibited a *naive moral* obliquity which would be regrettable in a child, bewildering in an adult, and is shocking and humiliating when it is found in the august halls of Congress

Specious catchwords and misleading phraseology may easily divert the minds of a busy people from the real points at issue in a controversy of this kind. "We built the canal; why should we not make the other people pay for it?" "The United States has invested nearly $400,000,000 in this enterprise; and why should we be called upon to play the part of the philanthropic benefactor by charging our own ships the same rate of toll as we charge the ships of other nations who have contributed not a single dollar to the great work?" The answer to this is that after a careful review of the situation, and in view of the advantages to be secured by the abrogation of previously existing treaties affecting the Isthmus, and in view of the pledge of Great Britain that the Canadian and Suez canals shall be operated on terms of equality, the United States did enter into a solemn agreement to operate the Panama Canal upon terms of equality, and the passage of the recent act exempting our ships has placed us in a most deplorable situation in the eyes of the world, as having committed an act of international dishonor.

Furthermore, the President speaks of the exemption of our coastwise shipping from canal tolls as economically unjust. It certainly is. Such exemption would be simply to divert a portion of the reasonable profits of the canal into the pockets of certain private corporations. We cannot shut our eyes to this fact The remission of these tolls will not mean the return of any profits of operation back to the National Treasury; and no amount of argument can prove that it will.

These, however, are entirely secondary considerations in view of the fact that the obnoxious act of last year has awakened throughout the world a distrust of our national good faith. "Let justice prevail though the heavens should fall," says the ancient adage, and a sentiment that was strong then is doubly binding today in an age that boasts of its advanced civilization.

There will be a fight to uphold this act exempting coastwise shipping—a bitter fight, no doubt; but with the President himself so strongly on the side of fair dealing, backed as he undoubtedly is, by the sentiment of the large majority of the nation, we look confidently for the repeal of an act which should never have been allowed to cast its shadow upon the history of our Federal legislation.

Pittsburgh's Smoke Bill

SMOKING is a costly habit, whether the smoker happens to be a man or a town. Persons who have hitherto regarded the "smoke nuisance" as mainly an æsthetic problem will be startled by the revelations of Mr. J. J. O'Connor, Jr., who has been investigating the smoke of Pittsburgh from the practical viewpoint of dollars and cents.

Here are the items of Pittsburgh's yearly smoke bill:

Cost to the smoke maker in the imperfect combustion of fuel (of which smoke is the outward and visible sign), $1,520,740 Better methods of stoking would not only do away with most of the smoke, but would effect a saving of 21 7 per cent in the present fuel consumption; in other words, about one fifth of the utilizable fuel of Pittsburgh factories now "goes up in smoke" and is a dead loss.

Cost to the individual citizen: (1) laundry bills, $1,500,000; (2) dry cleaning bills, $750,000. These figures do not represent the total laundry and cleaning business of the city, but merely the excess over what these items would be under ideal conditions of smoke regulation. The same principle applies to the figures quoted below in connection with other economic effects of the smoke nuisance. Pittsburgh is the greatest laundry town in the country, notwithstanding the fact that, with its large population of unskilled laborers, it has a greater percentage of citizens who do not patronize the laundries than almost any other city. The annual per capita laundry business is $3 12; about one third greater than that of the average American city Dry cleaning bills are far larger in Pittsburgh than in most other cities, despite the fact that Pittsburghers generally eschew light-colored clothing to such an extent that their city has come to be known as "the mourning town."

Cost to the household: (1) exterior painting, $330,000; (2) sheet metal work, $1,008,000; (3) cleaning and renewing wall paper, $550,000; (4) cleaning and renewing lace curtains, $300,000; (5) artificial lighting, $84,000. Houses in Pittsburgh are painted every three years, while in most other cities the houses are painted every six or eight years. The sheet metal of roofs, gutters, spouts, etc., deteriorates twice as fast in the smoky atmosphere of Pittsburgh as in cities of average freedom from smoke, and therefore needs to be renewed twice as often. It also needs repainting about twice as often. About 10,000 Pittsburgh households have their wall paper cleaned once or twice a year by a professional cleaner—a functionary who is unknown in most other cities. Pittsburgh walls are repapered every two years; in other cities from six to ten years is the average. Lace curtains are washed in Pittsburgh three or four times a year, and silk curtains every two to four weeks. The greatest cost in this connection is due to the rapid wearing out entailed in frequent washing. The necessity for excessive artificial lighting in a smoky atmosphere is obvious.

Cost to wholesale and retail stores: (1) merchandise, $1,650,000; (2) extra precautions, $450,000; (3) cleaning, $750,000; (4) artificial lighting, $650,000; (5) department stores, $175,000. Annual damage to merchandise due to smoke in typical stores, exclusive of department stores, ranges from $75 in a drug concern up to $1,500 at a haberdasher's, [illegible] at a grocer's, and $3,000 at a stationer's. The extra precautions to prevent damage to goods by smoke include additional labor, extra wrapping of cloth, books, or other articles when stored, screens to keep out dirt, coverings for goods, weather strips on windows, etc. The extra cost of cleaning requires no explanation. As to item (4), it is stated that 30 per cent of the artificial lighting in Pittsburgh is required by atmospheric conditions for which smoke is responsible. Under this item account is taken not only of the effects of diminished daylight, but also of the reduced efficiency of electric and other lamps resulting from the accumulation of soot on globes and shades. The losses experienced by department stores have been reckoned separately on account of the diversity of their stocks. These stores report damage to merchandise running up to $25,000, and other items in proportion.

Cost to semi-public buildings: (1) office buildings, $90,000; (2) hotels, $22,000; (3) hospitals, [illegible] The additional expense in these cases is analogous in its causes to that borne by private houses. It is found that Pittsburgh office buildings use 15 pounds of cleaning powder per thousand square feet per month, as against 11 required in New York, Boston, Philadelphia, Baltimore, or Washington.

The total bill foots up $9,944,740 per annum; and no attempt has been made to include such items as depreciation in the value of property, absence of various industries which are practically excluded by a smoky atmosphere, and, last but not least, injury to human health.

Rewards to Postal Employees for Inventions

THE appropriation act for the Post Office Department for the year ending June 30th, 1914, authorizes the Postmaster General to offer and pay periodically a cash reward for the invention, suggestion or series of suggestions for an improvement or economy applicable to the postal service submitted by one or more employees of the Post Office Department which shall be deemed the most valuable of those submitted and adopted for use, and for that purpose the sum of $10,000 has been appropriated

To obtain the reward the winning suggestion or invention must be one that will clearly effect a material economy or increase efficiency. The sum to be awarded as above to employees is in addition to their usual compensation. The total amount to be paid in any one month or for any one invention or suggestion is not to exceed $1,000.

It is provided that no employee shall be paid a reward under the act until he has quit-claimed any further claim by him or his heirs or assigns and executed an agreement that no application for patent has been made for any such invention. It does not appear that the act requires that the employee or employees submitting the invention or suggestion shall be an inventor or originator. The prohibition of patent application is unfortunate, since such application leads to the only means provided by law for the judicial determination of priority of invention in case of a contest. In any event, it seems unwise for the Government by one legislative act to deprive an inventor of the benefits of another act, especially since the invention submitted for postal purposes might have a greater usefulness outside of such service and its benefit to the limited service would not be lessened by its more extensive employment elsewhere. A committee has been appointed by Postmaster General Burleson to consider and pass upon the merits of such improvements as may be submitted under the provision of the act.

The Problem of Three Bodies.

THE mathematical problem known as the three bodies has resisted the attempts to solve it made by mathematicians from Lagrange to Poincaré. It has now at last been solved. This immensely difficult problem seems very simple. The problem is to express the motions of three bodies of any masses under the action of their mutual attractions, the attractions obeying, of course, Newton's law of gravitation. Poincaré, the great French mathematician, who has just died, did an immense amount of work on this problem, and although not completely solving it, obtained some very valuable results. He showed that in certain circumstances the bodies would be in the same positions again and again; in other words, that there existed periodic solutions. He also showed that a very remarkable case could exist where the bodies would first describe orbits which were nearly periodic, then gradually depart from the periodic form, and then again, after an immense lapse of time, approach the periodic form. But all these solutions broke down when the bodies actually came into collision. It has been reserved for Mr. Sundmann, astronomer at Helsingfors, to evolve a solution which remains true after the bodies have been in collision and thus to obtain a complete solution of this famous and seemingly unsolvable problem.

Engineering

Rapid Loading of a Steamer.—What is surely a record for speedy loading is that held by the Great Lakes steamship "William E. Corey," which when at Two Harbors, Minnesota, took 10,100 tons of iron ore into her hold in 26 minutes. The "Corey" is of the hopper bottom type of construction.

New York Harbor to Get $500,000.—A good start in the improvement of New York harbor has been made through the grant of $500,000 by Congress as an initial appropriation for the East River improvement project, recently urged by the Mayor of this city. The project calls for blasting away Coenties Reef and Diamond Shoal off the Battery, and the removal of other rocks in the river which have proved dangerous to navigation.

Increasing Size of Steam Turbines.—There is an extraordinary development taking place in the size of the individual unit in the field of steam turbines. We were commenting a short while ago on the fact that a unit of 20,000 kilowatts had been built; yet during the past year one of this size and another turbine of 25,000 kilowatts have been built, and it is stated that orders have been placed for four of 30,000 kilowatts and one for 35,000 kilowatts.

Three Boatmen to Each Lifeboat.—It is gratifying to note that the Seamen's Bill provision of "two deckhands to each boat" has been checkmated by the provision of the International Conference that there shall be "not less than three efficient boatmen" for every lifeboat carrying sixty persons and more for larger boats. This will result, as it should, in firemen, stewards, coal passers and other members of the crew qualifying in the handling of boats.

Larger Cylinders for Locomotives.—The Test Department of the Pennsylvania Railroad has been carrying on experiments with superheater locomotives, as a result of which they have determined that when a locomotive is converted from saturated to superheated steam, her cylinders should be enlarged. The results obtained show that, to secure maximum economy, the cyliners should be enlarged to such an extent that the maximum indicated horse-power will be developed at a cut-off not exceeding 30 per cent.

Thousand Foot Drydock for Navy.—In his testimony before the House Naval Affairs Committee, Secretary Daniels advocated the construction at the navy yard, Norfolk, of a drydock of the internal dimensions of the Panama Canal, namely, 1,000 feet long, 110 feet wide, with a depth of 40 feet over the sill. Such a dock would accommodate the largest dreadnought that will ever be built for the United States Navy. That the dimensions are not too great is shown by the fact that some nations, at the present time, are building warships which are considerably over 700 feet in length.

Government Railway for Alaska.—The United States Senate is considering the Alaska Railroad Bill, which involves the expenditure of $35,611,000 for the construction of 733 miles of railroad from a point on the southern coast of Alaska to the Yukon River. It is intended to make only $1,000,000 immediately available. Possibly the Government will take over the 72-mile road which runs from Seward to the north, or the Copper River and Northwestern Railroad, 169 miles long, which runs from Cordova, making the one selected the first division of a general railroad system.

Tenders Derail Trains.—Mr. H. W. Belknap, of the Interstate Commerce Commission, commenting on a wreck last October in which 17 passengers were killed, and 130 passengers and 6 employees injured, finds that the derailment which caused this disaster took place at the forward truck of the tender. He states that on account of the comparatively short wheel base, high center of gravity, and movement of water in the cistern, consisting of surging back and forth and from side to side, the tender is subjected to overturning and derailing forces, which are aggravated by any irregularity which exists in the tracks. Derailments of this kind occur more or less frequently on every large railroad in the country, and they should be given the closest possible study to ascertain their causes and, as far as is practicable, eliminate them.

New Type of Arched Dam Construction.—A new dam has been built in the Big Bear Valley, which proves that, where suitable foundations can be found, it is not necessary to build the huge and costly solid gravity dam, which has hitherto been the prevailing type. The new dam consists of a series of thin arched walls, with the convex faces upstream, which abut against a series of parallel longitudinal walls extending down stream. The latter serve to transfer the thrust of the water to the ground. The new dam has a factor of safety of 13.5, allowing the crushing strength of the concrete to be 3,000 pounds to the square inch. Timidity alone has hitherto prevented engineers from building this type of dam, which is now shown to be perfectly stable, very much stronger than the gravity dam, and cheaper even than the single-arch dam which the present structure replaces at this site.

Electricity

A Wireless Determination of Longitude has been made in French West Africa between Konakry and Kissidugu. Astronomical observations were first made at the two stations; then the Kissidugu chronometer was compared with the Konakry electromagnetic clock by means of wireless signals; and the results were checked by a further set of astronomical observations.

Wireless at the Lindenberg Observatory.—The aerological observatory at Lindenberg, which is the headquarters of Germany's storm-warning service for aeronauts, has been equipped with wireless telegraphy. The new installation will communicate with the wireless outfits on aircraft, and will serve the double purpose of disseminating meteorological information and of warning aeronauts to look out for kite-wires in the neighborhood of the observatory. At night a fixed searchlight and a flashlight are to be used to indicate the position of the observatory, and further aid in preventing collisions with kite-wires.

Electric Automobile Charging Station.—The New York Electric Vehicle Association has issued a booklet containing a list of charging stations within a hundred-mile radius of New York city. Also a map showing the exact location of the charging stations. In the majority of cases under the charging station the following data are given: Maximum amperage available; maximum voltage available; hours during which service is available; prices charged for boosting. The booklet should prove invaluable to owners of electric automobiles in the vicinity of New York, and should do much toward the promotion of the electric vehicle for out of town use.

Efficiency of the Battery-driven Tractor.—About a year ago the Pennsylvania Railroad put into service in Jersey City, N. J., a battery-driven tractor to haul freight cars through the streets. Previous to that the work was done with horses. A report has recently been published on the cost of maintenance and operation of the tractor for seven months. The total cost, including interest and depreciation, is $4,627.88. Had horses been used instead, the cost for the same work would have been $9,179.10, so that the tractor shows a saving for seven months of $4,551.22. Seven thousand seven hundred and twenty-three cars were handled and the cost of the service per car was 0.938 cent, while the cost of the service per ton was 0.028 and per ton mile 0.067 cent.

Heat-storing Magazine.—An inventor in Stockholm, Sweden, has devised an apparatus for storing heat. It consists of a mass of heat-absorbing material, in which is placed a coil of resistance wire. Surrounding the heat-storing material is heat-insulating material, while at the top is a damper which may be operated to permit the heat stored in the magazine to radiate out of the top. The entire apparatus is inclosed in a heat-radiating cover. To facilitate the radiation of heat there is a system of air passages through the heat-storing materials. The apparatus is adapted to be used during off-peak periods, storing heat which may be used as needed. An experimental apparatus about a yard high, 25 inches long and 15 inches wide showed a storing capacity of about 25,000 kilogramme calories, while a temperature in the storing magazine of about 600 deg. Cent. or about 1,100 deg. Fahr. was obtained.

Electric Sterilization of Milk.—The sterilization of milk by electricity without injury to flavor or nutritive qualities bids fair to become a regular practice. Recent attempts to kill the bacteria in milk by brief exposure to the ultra-violet light from a quartz mercury-vapor lamp have attracted considerable interest, but these attempts have not resulted in success. The milk is so opaque to the rays that it was necessary to expose it in thin sheets and then a dangerous fraction of the bacteria escaped the killing process. Another objection has been that the necessary intensity of ultra-violet light gave an unpleasant taste to milk. Another process has been developed at the University of Liverpool under a grant from the City Council and the experiments, carried on for the past two years, are most promising. Exact details of the method have not yet been made public, but it is stated that a high-tension electric current is used and that the exposure is exceedingly brief. The taste of the milk is not changed in the least, nor is the "bouquet" lost. Expert dairymen testified that they could not detect any difference in treated and untreated samples. In fact, the City Analyst found no change in the composition of milk so treated or at least so little as to be negligible. It seems remarkable that the acidity did not increase. Naturally there was no coagulation. Heating was trifling. All pathogenic or dangerous bacteria were killed by the electrification, and it was stated by the scientists that perfect sterilization could be secured with longer treatment. The feeding tests so far have been made on kittens which grew fat on the sterilized milk. Guinea-pigs inoculated with tuberculous milk that had been electrically treated failed to develop the disease. The city of Liverpool has made the investigation official.

Automobile

Wanted: Method of Keeping Seats Dry.—In the city of London, where self-propelled 'buses form such an important part of the transportation system, difficulty has been experienced in keeping dry the outside seats. In consequence, the London General Omnibus Company, which operates by far the greatest number of 'buses, is inviting inventors to submit ideas to overcome the trouble. The ideas should be sent to the chief engineer of the company, whose address is 9 Grosvenor Road, Westminster.

Effect of Corseting on Upholstery.—It has been advanced by persons who are in a position to know that the styles in ladies' corsets exert a marked influence upon the design of automobile upholstery. This is explained by the fact that whereas one style of corset, in vogue to-day, may encourage a luxurious lolling position of the wearer, another style, in vogue to-morrow, may compel a severely upright position. Consequently designers find it incumbent to study other things besides automobile engineering.

Nothing New Under the Sun.—The illustration and description of an electric device to assist carburetion, which was published in our Automobile number, brings to mind that a device of a somewhat similar nature was used as long ago as 1903. It was applied to a surface carbureter on a motor bicycle and consisted briefly of a coil of iron wire wrapped inside the intake pipe. The wire was heated by passing through it a current of electricity from an accumulator. The device worked well but nearly caused an explosion owing to the fact that it created rather too much heat.

A Shortcoming of Cooling Systems.—Despite the plane of perfection to which the modern automobile water cooling system has been brought, the fact nevertheless remains that it has an inherent defect that should be plainly apparent to anyone who has eyes to see. The fan behind the radiator is designed to draw air in through the tubes of the cooler, and because its action cannot be made discriminatory, it continues to invite inside all manner of dust and dirt and winged insects. One foreign manufacturer has eliminated this trouble by causing the air drawn in at the front to be expelled at the sides of the radiator. With the widespread use of radiators, it seems that there is room for the exercise of ingenuity, which almost certainly would be rewarded, for the need of a better method of directing the circulating currents of cool air is real.

Things that Militate Against Pneumatic Engine Starters.—Size and weight of parts, together with a degree of complexity that is permissible only in view of the result accomplished, have militated somewhat against the general use of compressed air engine starting devices. Coupled with these disadvantages there always has been, and probably there always will be, the objectionable propensity of compressed air to escape its bonds on the slightest provocation. It is not the easiest matter in the world to confine compressed air in such a way that the pressure will remain practically constant for long periods, and when the problem is augmented by subjecting the apparatus to the continual vibration that is impossible of elimination in the automobile, the difficulties attendant upon the satisfactory use of air as an engine starting medium are considerably increased.

Electric Lights at Low Cost.—While it goes without saying that an electric lighting system is a most desirable feature in an automobile, the high prices at which most of such systems are offered to the public precludes their use by many owners. Realizing this, a well-known manufacturer of automobile specialties has just brought out a new electric lighting system, of novel construction, the principal feature of which is that it can be installed easily and sells for only $12. The system comprises a dash lamp, a tail light and a portable trouble lamp. The body of each lamp is made of hard rubber instead of metal and contains a powerful lens. The tail lamp has a red lens for the warning signal and a slot underneath, with a white light for illuminating the license plate.

A New Type of Motor Vehicle Tire.—There has appeared upon the market a brand new type of automobile tire in which rubber or rubber compounds of any kind are conspicuous by their absence. Despite this fact, it is said that the shock absorbing proclivities of the tire are quite equal to those of the rubber variety. The tire is composed wholly of cotton fabric which is made waterproof and compressed into a steel rim, the threads running diagonally from tread to base. No adhesives, binders or compounds are used. A somewhat peculiar characteristic of the tire is that after use it picks up a coating of grit and small particles from the road which become partly imbedded in the fabric and sustain much of the wear. The tire has a shock absorbing quality somewhat akin to that of a bag of meal that is struck a heavy blow; rebound is missing. The tire weighs approximately 30 per cent less than a solid rubber tire of the same size. Although developed primarily for commercial vehicles, the tire can be used on pleasure cars.

A Flat Band With Only One Surface and One Edge

By Carl Hering

SOME intellectual entertainment may be obtained by taking a strip of paper, say an inch wide and 8 or 10 inches long, and asking others to manipulate it in some way so that it will have only one surface and one edge. Originally it has two surfaces and four edges; by pasting the two ends together so as to produce an ordinary ring like a napkin ring, it will still have two surfaces, but now only two edges.

Although generally thought impossible at first, it is really quite simple. The solution consists in pasting the two ends together as though such a ring were to be formed, but first giving the strip a twist of half a turn. The former two surfaces and two edges will now form only one continuous surface and only one continuous edge.

Further entertainment may be obtained by cutting the ring in the direction of the length of the band, as though forming two narrower rings of it, and asking whether these two rings will be linked or unlinked. The guesses will generally be evenly divided, but both are wrong, as it forms only one ring of double the diameter. If the large ring thus formed is again cut in the same way, one might now expect it to double in size again, but it will surprise one again by this time forming two rings doubly interlinked. When the original is similarly cut into three parts it will form one small ring and one large one interlinked with it. By giving the original strip a whole twist instead of a half, it will have two surfaces and edges and will cut into two rings linked once. Three or five half twists again form a ring with but one surface and one edge, and will cut up into other though more complicated oddities, one of which is a single ring with a knot tied into itself, somewhat resembling a pretzel.

The single surface ring is also of interest as a mechanical and mathematical oddity. To show its true shape when it is formed according to a regular law, the writer had a model constructed. In its simplest form this law is, to consider the center line of the ring to be a circle, and the band is then described by a short line perpendicular to the circle and bisected by it, moving along the circle and at the same time turning or revolving around that part of the circle as an axis, so that when it has made its complete circuit of 360 degrees around the circle it has made a half turn around its axis, that is, 180 degrees, the two movements being, of course, perfectly regular, one degree of revolution for every two degrees of advance.

An ordinary strip or band of paper or metal made into such a ring as described above, will not take the shape of the regular form, as it would have to bend edgewise to do so, because one edge would have to be greatly stretched and the other greatly compressed. A paper or sheet metal ring will take an oval shape, in which the helical twist is mostly in one half and the cylindrical bend mostly in the other half.

The correct shape can be obtained only in a model free from any internal strains. Hence it was made of a tore or thick round ring of wood, of circular cross section, as shown in Fig 1. On the outside of this was then drawn the spirally shaped edge, and the part not wanted was cut away. The edge of the finished ring is therefore a part of the original surface of this tore. The band ring, thus formed, is shown in Fig. 2. Being made of wood, it had to be given considerable thickness for the sake of strength. Bands running lengthwise were painted on it in order to show its properties to better advantage. The white line at the center forms a circle (if the thickness is neglected), and if all the rest were cut away, this portion would form a circular ring whose solid part has a square cross section, and a twist of half a turn.

If a narrow strip of paper were laid on the surface of this white band, completely covering it, and had its beginning fastened to its end, it would when removed form a single ring of double the diameter of the original. If the same were done with the bands near the edge, two rings of double the diameter would result.

If the model were cut through between the white band and those near the edge, and supposing it were made of some flexible material, a large and a small ring interlinked with it, would be produced. When the width of the band is made greater, for the same center line diameter, the oddity of the shape becomes more pronounced. When the width equals the center line diameter the edge passes through the center where it is, for a very short distance, coincident with the axis. When the width is increased still more a peculiar reversal of curvature takes place. A limit to the width is reached when the edge touches the other side of the ring, that is, when the width is nearly twice the diameter, depending on the thickness of the band.

When revolved on its axis it produces a flow of air, hence acts as a noiseless fan as distinguished from those with blades which produce a succession of puffs. It also acts as a mixer for concrete or ice cream.

The peculiar surface of this ring occurs in nature in the conch shell, though somewhat imperfectly. A round rubber ring like an umbrella ring, when split in the direction of the planes of this single surface ring, will form a ring of double the diameter.

When such a ring is cast of a soft metal like lead, then cut in the plane of the axis, unrolled and untwisted, so as to form a flat strip, it has the shapes shown in Figs. 3 and 4, differing in where it is cut. Hence if a piece of sheet metal is cut to one of these shapes and then has its ends brought together, after giving it a half twist (*a* to *a*, *b* to *b*, etc.) it will approach the regular form. The horse-shoe template (Fig. 4) is perhaps the easier of the two to manipulate, as the curvature is then least at the joint.

FIG 6—ONE FACED BAND OF TRIANGULAR SECTION

Some curious single-surfaced, single-edged bands.

A still more curious single surface ring is shown in Fig. 5. The cross section here is a square, as though made of a bar of square cross section, but instead of being given a half twist it is given only a quarter twist. At first sight it looks as though it should have four sides and four edges, but it has only one of each.

If cut lengthwise, dividing the square cross section into halves, it will be found necessary to cut twice around the circle, and it will then (if of flexible material) form one ring of four times the diameter and one quarter of the cross section. A round rubber ring can thus be split to form one four times as large. If the edge of the ring, Fig. 5, is cut off by a slanting cut, it will form a large ring while what remains will be a ring of the original diameter.

By making the section a regular hexagon, octagon, etc., and giving it a twist of one sixth, one eighth, etc., respectively, the ring will appear still more odd and deceiving, and if similarly cut, would form a ring six, eight, etc., times as large. The cross section of this form must of course be a regular polygon.

The one having a triangular section (Fig. 6) is of special interest, as there is a regularity or symmetry in its irregularity, and the twists may be made any multiple of one third. It cuts up into a variety of rings depending upon the direction of the cut.

When any of these rings, particularly those of the latter kind, are revolved around their axis, they will give a very good reproduction of the characteristic revolution of a vortex ring, more commonly represented by the usual smoke ring. This is made more evident by painting bands of different colors on them, like those on the models here shown.

The rings will then appear to be revolving around their circular center line as an axis, precisely as the vortex ring does. In fact, they then actually constitute a kind of vortex ring and ought therefore to have some of the properties of such rings, like rolling through air or water in the direction of their axis, or if this axis is at rest, then moving the air or water in the opposite direction, therefore acting as a propeller, though as an effective propeller it is subject to improvements in design.

The center of gravity seems to be at the center of the circular axis, hence such rings revolve smoothly. By securing to the ring a shaft in the line of the axis, a top may be made which when spun at a low speed will show the vortex ring motion quite nicely.

Fresh Discoveries Regarding Red Blood Corpuscles

SOME interesting observations on red blood corpuscles have been made by MM. von Liebermann and von Fillinger of Budapest, according to *Kosmos*, to the effect that many diseases which are not themselves, properly speaking, blood diseases, nevertheless produce injuries in these corpuscles, such injuries being observable in a salt solution, though not discernible under the microscope. They first made a suitable salt mixture in which the red corpuscles of a healthy man remained unaltered, one drop of the blood being placed in five cubic centimeters of the solution. This was verified with a number of healthy persons, and then tests were made with the blood of persons suffering from various diseases, among those mentioned being cancer, inflammation of the lungs, and inflammation of the breast. In all these cases the red blood corpuscles immediately dissolved, i. e., they gave up their red coloring matter to the solution. In other words, *hemolysis*, or dissolving of the blood, took place. The conclusion drawn is that probably in *all* diseases, and certainly in those named, the red blood corpuscles, though seeming quite sound when examined under the microscope, have in reality sustained alterations or injuries robbing them of their resisting power.

We must conceive that they have been poisoned by the virulent metabolic products which circulate in the blood of all diseased persons, and the fact that they were injured by such various diseases well illustrates the fact that the illness of any organ sympathetically affects the whole organism.

Another valuable observation was made in this connection. It was found that the injection of alcohol produced temporarily a similar effect on the red blood corpuscles. They were, in fact, poisoned by the alcohol for a time.

The Theory of Gravity

IN an extremely interesting paper on this subject in the *Philosophical Magazine*, Prof. McLaren considers the universe as possessing four dimensions, and also retains the notion of time. The universe so considered is regarded as changeless, but not timeless, and differs in this respect from Minkowski's four dimensional universe. Prof. McLaren considers that throughout the universe there is but one ultimate substance. This substance has, however, two forms, "matter" and "ether," which are exclusive one of the other. Matter is a region where the fluid grows or decays. This theory strongly resembles that proposed long ago by Bernard Riemann. Prof. McLaren pleads for an unprejudiced examination of these views, revolutionary as they are, in view of the widespread feeling that there is something amiss with the classical mechanical theories of matter.

The Lighthouse Reservations on the Great Lakes are able to grow all the white cedar needed for spar buoys in their district.

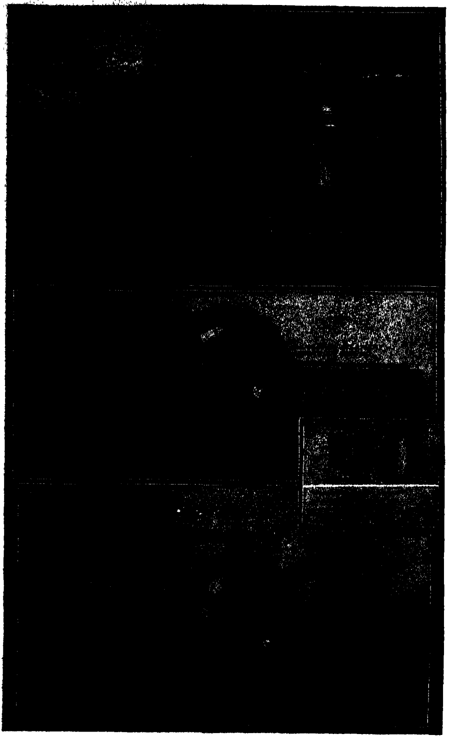
The U. S. Fleet Collier "Jupiter"

THE fleet collier "Jupiter" was authorized by Congress, May 13th, 1908; the keel was laid October 18th, 1911, and the ship went into commission April 7th, 1913. She was built in conformity with the rules of the American Bureau of Shipping. She is of twin-screw, single-deck type, and was designed for a speed of 14 knots with 5,500 shaft horse-power, on a draught of 27 feet 6 inches and a load displacement of 19,240 tons. She carries 11 officers and 148 men. The general dimensions of this large collier are: Length over all, 542 feet; beam, 65 feet; mean draught, 27 feet 6 inches.

She has four decks forward and five aft, the forecastle and poop each being one deck higher than the upper deck. Amidship in the cargo space there is but one deck. There are nine water-tight, five oil-tight and two non-water-tight athwartship bulkheads. There are thirteen cargo holds. Those that may be used for oil are in pairs, one on each side of the ship, and they are divided by a fore-and-aft bulkhead. The holes that are used for coal extend only the width of the ship and are of the self-trimming type. The coal-handling gear calls for a delivery of 100 tons per bucket, per hour, when the gear is operated by a winchman with one week's experience. The booms and the rigging are supported from towers, each consisting of two A-frames tied together with X-braces. There are seven of these towers in the waist of the ship and one on the superstructure. There is a single A-crane between the two after towers, which serves as an additional support for the fore-and-aft trolley ways which run between towers 6 and 8. At each tower except towers 1 and 8 there are four booms, two on each side of the tower. The thwartship cable span, which acts as a track for the trolley, runs from a boom head on one side of the ship to a boom head on the other side, and the cable span gives a travel of twenty feet beyond each side of the ship, and has sufficient height to clear the deck of a battleship twenty feet above the collier's deck. There are two winches, one clam-shell bucket of one ton capacity, and a trolley for each pair of booms. The hoisting engine is twin-cylinder with a 10-inch diameter and 12-inch stroke; it runs in one direction only, and has a throttle operated by a foot lever. The trolley engine is twin-cylinder with 8½-inch diameter and 10-inch stroke; it has reversing links for changing the direction of rotation, and this is operated by a hand lever; the throttle being operated by a foot lever. Each bucket requires two men to operate it, one man to open and close and hoist and lower and another to traverse.

For filling and emptying the cargo holds with oil there are four 6-inch gate valves on the forecastle and 6-inch wrought iron pipes which lead from these valves down through the forecastle, where two on each side join into an 8-inch pipe, and these two 8-inch pipes in turn connect to a 10-inch riser which leads down into the pump room. In the pump room are two 14-inch by 12-inch by 12-inch horizontal duplex pumps, rated at 1,000 gallons per minute each.

The main engines are of a new type, consisting of one Curtis turbo-generator, two induction motors, two water-cooled rheostats, and one main switchboard. The turbo-generator furnishes power for the motors, the function of the generators and motors being solely that of a reduction gear. All changes of speed are made by changing the speed of the turbine, thus varying the frequency of the generator, and consequently the speed of the motors. The speed reduction ratio is therefore 1 to 18. The object of this installation is to obtain the high efficiency of high-speed turbines and the high efficiency of low-speed propellers The weight of the installation is less than that of the standard type of ship drive, and the space also is less than in any of the present installations of marine turbines or reciprocating engines.



A most important advance in the development of the X-Ray is the invention of a new Roentgen tube by Dr. Coolidge. As a result of the invention the time of exposure is reduced to but a fraction of what it has hitherto been. The tube is so flexible that it can be operated at a penetration so slight as to show the fine blood vessels of the hand or foot at one instant, while at the next it can be increased so that a penetration far exceeding anything possible with the ordinary tube can be secured.

The new high efficiency Coolidge X-Ray tube.

The New Coolidge Roentgen Ray Tube

By Herbert T. Wade

IN using the Roentgen ray tubes the penetration of the rays has hitherto been controlled by regulating the vacuum of the tube, and, except for minor details of construction and methods for such regulation of vacuum, there has been little fundamental difference in the tubes used A new tube, however, designed by Dr. W. D. Coolidge, at the great research laboratories in Schenectady, has recently been developed in which an entirely new principle is involved. This tube gives a pure electron discharge and serves to reduce, in great measure, the actual time of exposure; in fact, it has been considered

Modern Hand-Grenades

The Aasen Hand, Rifle and Mine Grenade

By Major H. Bannerman-Phillips

THE use of the "grenade" in modern warfare is a revival of an ancient practice, and the term was first used by DuBilley in reference to the siege of Arles in 1536. Until the end of the seventeenth century soldiers of the line were trained to throw grenades by hand, hence the name "grenadier." The grenades were hollow balls of iron or other metal, or annealed glass, about 2½ inches in diameter, filled with gun-powder and fired by a fuse which was lighted before throwing them. Soldiers of long service and acknowledged bravery were selected for grenadiers, of whom there were comparatively few in each regiment of infantry at first, though later there were grenadier companies, and still later the "grenadier company" of each battalion took priority on parade in both the English and French armies, though they no longer carried the little spherical projectiles which first gave them their name, and were mainly distinguishable by the height of the men, and their special uniform or head-dress

Hand grenades were used to a large extent during the Russo-Japanese war, more particularly by both sides when fighting at close quarters during the assaults on the various forts at Port Arthur. The Japanese made them in the form of a small tin cylinder, about 8 inches long and 3 inches in diameter, filled with a high explosive and with about 7 inches of safety fuse projecting through a hole in the lid. This fuse being lighted before the grenade was thrown would allow about 9 seconds for the missile to reach its destination previous to exploding, but would not burn long enough to allow an enemy to pick it up when fallen and hurl it back before it had done its work. This was, in a manner, harking back to primitive methods, and any small closed tin receptacle would serve the same purpose if it were charged with gun-cotton or dynamite and a detonator and fuse attached in the usual way. The effect of these hand grenades when exploded in a confined space is sometimes very deadly. For instance, on one occasion a Russian guard of no less than seventeen men were killed inside a guard room by an improvised grenade, consisting of a fused slab of gun-cotton which was thrown through one of the windows.

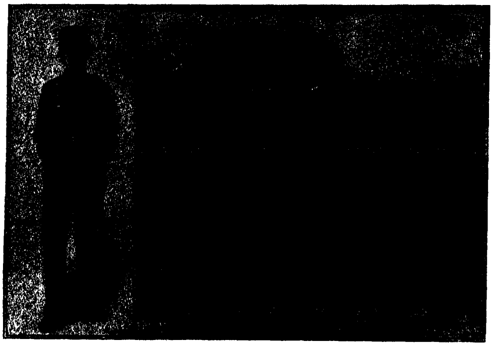
So effective is this class of projectile when used under suitable conditions such as by storming parties on siege works or in small sorties by the besieged with the object of attacking sap-heads and approaches, that the Japanese found it necessary, when working in the trenches close to the enemy's line, to protect themselves by special wooden frames about 7 feet by 4 feet with stout wire netting projecting above the parapet. It is not to be wondered at therefore if inventors have endeavored of late years to produce grenades which while deadly to the enemy on explosion shall yet be capable of being safely handled by the thrower. The Aasen hand, rifle, and mine grenades are constructed to meet these conditions, as will be seen from the following particulars furnished by the manufacturers. Our cover illustrates both the rifle and howitzer form of the Aasen grenade. Of the illustrations on this page, Fig 1 shows the manner in which a soldier carries hand grenades on his person; Fig. 2 is a picture of a volley of howitzer grenades, in which case the grenades are discharged from a fixed stand with various degrees of inclination to the horizon; and Fig 3 pictures several types of grenades In a recent number of the SCIENTIFIC AMERICAN, the Aasen mine grenade was described and illustrated—a bomb which is prevented from rising above a predetermined height by means of a chain secured in the ground, and electrically fired.

The methods and results of tests carried out with the various forms of weapon and projectile at a private practice range used by the inventor in Copenhagen in Denmark are shown as follows:

A. Volleys of rifle grenades were fired by 7 men from behind covers against a group of 80 double-figure targets of wood distributed under cover over an area of 900 square meters. Results of the first volley; as shown by numerals on the targets, 93 hits on 43 targets. After the third volley seventy-two targets showed 168 hits. The range varied between 300 and 400 meters.

The rifle grenade complete weighs about 550 grammes and contains 72 bullets each weighing 2.5 grammes and about 70 grammes of explosive. These 72 projectiles cover an area of at least 40 to 50 square meters. The rifle grenade can be used with an ordinary military rifle at all distances up to about 400 meters. The destructive efficiency of the grenade is due mainly to the fact that the interior percussion mechanism causes it to explode immediately on impact and before the grenade has time to bury itself in the ground.

B. Salvoes from seven "howitzers" were fired at a group of 80 figure targets placed within an area of about 900 square meters. The results of the first salvo are shown by numerals recording the hits on each target. After the fourth salvo 68 figure targets had received 143 hits between them. The distances varied between 280 and 310 meters. The grenades used were of type *C*, each weighing 1 kilogramme and containing 215 bullets and 200 grammes of explosive (Ecko). This *C* type can be thrown by hand up to 40 meters and with the "howitzer" or discharging tube up to 300 meters. The "howitzer" weighs 12 kilogrammes and can be carried in a special case as one would carry a rifle. The bullets cover an area of at least 80 square meters in the shape of a half-circle, and travel forward and sideways after the bursting of the grenade, but none are driven backward toward the thrower. These grenades are consequently of great value for fighting at close quarters. They are so constructed as to be secure from bursting until they have traveled at least 8 meters on their way toward the target.



1. Soldier equipped with hand grenades. 2. A volley of howitzer grenades. 3. Several types of grenades

Types of grenades to be use in modern warfare.

C. A single volley of 7 hand grenades, namely, 3 of type *A*1 and 4 of type *C*, thrown by hand from behind covers at the targets shown in sketch. Result: 119 hits on 33 targets as shown by the numerals on the latter. The hand grenade, type *A*1, weighs about 1 kilogramme, contains 190 bullets of 2.4 grammes each and a charge of 110 grammes of explosive (Ecko). The percussion mechanism and safety arrangements are similar to type *C*, but the bullets fly in *all* directions on the bursting of the grenade, consequently it is only suitable for throwing from behind cover.

D. Three mine grenades were buried underground in a triangle at 30 meters interval in the midst of a group of about 145 double-figure targets of wood, which were distributed over an area of about 2,700 square meters. The grenades were fired singly, one after the other (by electricity), and the results were about 700 hits among 120 targets, as shown by numerals.

The mine grenade weighs about 4 kilogrammes and contains 400 projectiles each weighing 3.8 grammes and 200 grammes of explosive (Ecko). The 400 projectiles cover a beaten zone of at least 800 square meters. The grenades are buried about half a meter underground, together with the electrical connections, so that they are absolutely invisible to an enemy. On being fired they rise about three fourths of a meter above ground before bursting and their projectiles are then driven in all directions parallel to the ground surface. At a distance of 10 meters they will pierce at least 100 millimeters of wood and will kill up to [illegible] meters. A hundred soldiers can lay out a protective line of these mine grenades 4,000 meters in length in less than two hours.

The Recent Earthquake

AT this writing, a few days after the earthquake of February 10th, it is impossible to present more than a fragmentary account of the occurrence, or to be sure that much of the information now available on the subject is accurate. Even if the disturbance had been far more severe, entailing immense loss of life and property, we should be in much the same state of uncertainty. As matters now stand in this country, it is nobody's business in particular to collect and digest reports of earthquakes immediately after their occurrence, when all the facts are fresh in the observers' minds, and a high degree of accuracy in the record is therefore attainable. Seismographs are in operation at a few widely scattered points, but there is no systematic and prompt interchange of their records, analogous to the process of assembling meteorological observations by telegraph which has been brought to such perfection by the Weather Bureau. In short, the United States Seismological Service is still only a dream; just as the national weather service was for the far-seeing American scientists of half a century ago.

The earthquake in question occurred a little after half-past one o'clock in the afternoon. The seismograph at the American Museum of Natural History, in New York, registered preliminary tremors beginning at 1:33:5; the first well marked shock at 1:33:25; the maximum at 1:33:45; and trailers continually until about 1:35. The macroseism lasted hardly half a minute. Shocks perceptible to the human senses occurred in eastern Pennsylvania, New Jersey, New York State, New England, and lower eastern Canada. The epicenter appears to have been somewhere in the lower St. Lawrence Valley. So far as may be gathered from press dispatches, it cannot have been very distant from western and northern New York, where the disturbance reached an intensity of 6, or possibly 7, on the Rossi-Forel scale. At Binghamton, Penn Yan, and Syracuse walls were cracked, unstable objects were thrown about, and a mild panic occurred among the inhabitants. In Manhattan very few people were conscious of the shock, but it was distinctly perceptible in parts of Brooklyn, owing evidently to local instability of the soil. After-shocks were reported from New England on the 11th.

The whole phenomenon was one which would have attracted little attention if it had occurred in one of the great seismic belts of the earth. Happily macroseisms are rare in the eastern United States; though the presence of extensive fault-lines running practically the whole length of the Appalachian Valley, and northward makes it certain that perceptible and perhaps locally destructive earthquakes will occur in this comparatively favored part of the world from time to time in the future as they have in the past. Their effects will depend upon surface texture. The same intensity of impulse that wrought serious disaster in Charleston, S. C., in 1886, would probably leave New York city unscathed; the former town being built on soft and largely "made" land; the latter on thoroughly consolidated soil and rock.

Mine Disasters in the United States.—The statistics of coal-mine fatalities in the United States during last August, just published by the Bureau of Mines, show 230 deaths, as compared with 211 during the same month of 1912. During the first eight months of 1913 the fatalities numbered 1,673, as compared with [illegible] during the corresponding period of 1912. These [illegible] figures emphasize the importance of the [illegible] and investigations in which the Bureau of Mines has taken the lead.

The Value of Radium

TO scientific men radium has been a subject of absorbing discussion from the moment it was discovered, but it is rapidly becoming a matter of considerable interest to the general public on account of its therapeutic value. Its extreme rarity and the mysterious and not yet wholly understood qualities and activities which are peculiar to it, added to the enormous difficulty in obtaining even small quantities of the precious metal, and the extraordinary prices quoted for it when obtained, invest the subject with a glamor which appeals to the romantic side of human nature. Consequently, every fact concerning radium, and every fresh development of our knowledge of its properties, are noted with intelligent curiosity by the great majority of newspaper readers, to whom chemistry is a closed book and physics a matter of no concern.

Its recent effects in the treatment of cancer have called forth manifestations of world-wide satisfaction, and "radium water" is now being tried for the treatment of gout and rheumatism. This is the ordinary fluid known to chemists as H_2O, and to the layman as simply "water," but it is charged with the emanation, or gas given off by radium in the form of radium salts. The method of preparation is to dissolve the salts in water, which is then sealed up and left for about 28 days, during which the emanation is produced. It can then be expelled by boiling and passed into another measure of water, endowing the latter with radio-active qualities. Unfortunately, this radio-activity only endures for a short time, and in 96 hours, or thereabout, the preparation has diminished in efficiency by more than fifty per cent. Water with a certain amount of inherent radio-activity can be obtained from springs, and dust with the same characteristics is also found in certain localities. In those cases the water must be drunk fresh from the spring, but the dust appears to retain its curative quality as a dressing for wounds or otherwise therapeutically, in the form of plasters and poultices, for a considerable time after removal from the spot where it is found and when it has been subjected to the influence of radium in the ordinary course of nature. In Great Britain, and presumably elsewhere, the usual course adopted in treatment of disease by radium water is to make up for the diminishing effect by increasing the quantity taken as the treatment proceeds, and as the water prepared thus is producible at a cost which is infinitesimal as compared with that of radium itself, it promises, if successful, to be a boon to suffering humanity.

It is to be hoped that as our knowledge of the effects of radium on cancer increases we may find some cheaper method of extracting it from the substances which contain it, for at present the cost of the process is simply prohibitive. So far it has been found in pitch-blende, autunite, carnotite and torbenite, owing to their containing small quantities of the metal uranium, which itself contains the much sought-for radium in the proportion of 1/3,000,000.

A ton of the ore above referred to will contain some ten milligrammes of radium and Madame Curie's standard sample contains twenty-two milligrammes of pure radium chloride. European transactions in this valuable product usually include an agreement providing that the article delivered shall be compared with the standard at Sèvres or the analogous standard at Vienna in the keeping of the Austrian Academy of Sciences.

The current market value of radium in Europe at the present moment works out at somewhere about $2,500,000 per ounce—not that any individual or corporate society is fortunate enough to be in possession of such a quantity.

How a Cream Separator Speed Indicator Saves Money

"THERE! If you've been turning your separator at that speed all the time, then with your twenty cows you've lost $524.10 worth of butter in one year!"

The above is the astounding statement made by a dairying authority to a farmer whom he had been watching operating his cream separator.

When you buy a cream separator you will find on the crank handle, in large, raised letters instructions something like this—"55 revolutions per minute." Or it may read 45, or 50, or 60; it varies on the different makes of separators.

Suppose, for example, that yours reads "55 revolutions per minute." What does that mean? It means, whenever you operate that cream separator you should turn the crank handle precisely 55 turns to the minute.

The manufacturer has tested his separator under every possible condition, in order to know the exact method of operation at which it gives the greatest degree of efficiency.

But how does the dairyman know how many times he turns it? It is just as impossible to guess accurately the speed of his cream separator as it is to guess accurately at other things.

At a Wisconsin dairy farm the superintendent said he always "guessed" the proper speed. When asked how his helpers operated the separator he replied that, after he had broken new men in, they also could operate it at approximately correct speed. In order to prove his statement, one of his helpers was asked to turn the separator at the speed he usually operated it. The number on the crank handle read "48 revolutions per minute." But the helper made only *28 turns* to the minute.

This proved how absolutely wrong the superintendent was in supposing that he, or any of his helpers, could tell when they were turning the crank handle exactly right, *or anywhere near*, what the manufacturer told them it should be turned. Here were pounds of butter-fat going to the hogs daily, just because he "guessed." And if he will feed calves and hogs with butter-fat worth 30 cents a pound, when he can feed them *better* on two and one half pounds of corn meal and skim milk, then that shows how much the dairymen have to learn to get all the profits out of dairying and farming.

At the Purdue Experiment Station, Indiana, very exhaustive tests were carried on to show the tremendous losses through wrong operation of cream separators. A separator was run at its normal speed of 55 turns to the crank handle per minute. Fifty pounds of milk were run through the separator. At this speed, it delivered 45 pounds of skim milk and 5 pounds of cream. This cream tested 2.11 pounds of butter-fat. When the speed was increased to 75 turns per minute, the skim milk discharged was 46½ pounds, reducing the cream to 3½ pounds. And the amount of butter-fat was slightly less than when the separator was turned at normal speed.

Next, a test was made by letting the speed of the machine drop down to that at which it has been found the average dairyman operates a cream separator, with the astonishing result that the discharge from the "cream" spout went up to 9½ pounds, but it tested *only 11 per cent of butter-fat—only* 1.04 pounds *of* fat out *of* 50 pounds of milk, as against 2.11 pounds when the separator was operated correctly.

Dairymen are losing *from* 20 *to* 50 per cent of *their* butter-fat with every operation. This is a matter of waste that is simply appalling when the aggregate figures of all the dairymen in this *country* are considered. It probably runs into thousands of dollars *with each daily milking.*

Now a speed indicator has been invented to be applied to cream separators, mounted on the crank shaft of the separator. As the separator handle is turned, the exact number of revolutions per minute that the crank handle is making is shown in a definite figure, so that it may be read at a glance. There is no calculating to be done; it is only necessary to keep on turning the crank handle until the proper speed is reached, and then continue at that exact speed throughout the separation. This eliminates all guess-work entirely. It also adds zest to the otherwise monotonous operation, particularly where the separation requires upward of an hour's turning, as its does in many instances.

Is the Earth Drying Up?

IN a recent paper before the Royal Geographical Society Prof. Gregory discusses this question. It is believed by many that there is a progressive world-wide change toward a greater and greater degree of dryness. Prof. Ellsworth Huntingdon believes that there are alternations of climate, it being sometimes drier, sometimes moister, but with a tendency to become generally dried. Mr. R. Thirlmere believes that the climatic changes take place in cycles, each cycle lasting 2,000 years or more, and that our world is at present cooling. From an exhaustive analysis of the evidence Prof. Gregory doubts the theory of a universal tendency toward drought, although there may be local variations. The strongest evidence for the desiccation theory is derived from Central Asia, the majority of travelers who have visited that region being convinced of its progressive change to a state of greater and greater dryness.

Absorption of Light in Space.—If one divides the known nebulæ in groups according to the dimensions of their apparent diameters and one also notes their intrinsic brightness, it is clear that their apparent diameters should decrease as the distance increases. Their brightness, on the other hand, will diminish with increasing distance only if interstellar space absorbs light. As the result of a great number of observations a correlation between brightness and apparent diameter has been observed, and is so marked that it is impossible to put it down to chance or to some systematic error. It appears that there is a real absorption in space, and if more precise descriptions of the nebulæ were available the law of absorption could be assigned. Another indication in the same direction is that the mean brightness of the nebulæ varies from one part of the heavens to another in a marked manner and in the same way as the stellar density.

A Problem in United States Coins

To the Editor of the SCIENTIFIC AMERICAN:

Permit me to offer the following solution to the problem submitted by Theodore L. DeLand in the SCIENTIFIC AMERICAN of February 7th, on page 117, and entitled "A Problem in United States Coins." I have not yet thought of an algebraic formula by which the problem could be solved, but have reasoned it out by a process of elimination.

The highest common factor of 200, the number of coins, and 50,000, the value of those coins in cents, without making the resulting quotient approximately equal to or less than the number of different kinds of coins, which would be absurd, is 10. The resulting quotients are 20 (coins) and 5,000 (cents). Hence, if twenty coins can be found, subject to the condition stated, whose combined values are 5,000 cents, it will only be necessary to multiply the number and the value of each kind by 10 and add the resulting similar products to get 200 coins and $500 for the final result.

Considering only the four gold coins now minted, there are only ten possible combinations in which the values are less than 5,000 cents. If the number of coins in each combination be subtracted from 20 and their value from 5,000, it will be found that four of the possible ten combinations can be eliminated, because if all the coins in each case were fifty-cent pieces, the largest coin now left to be considered, their combined values would not be as large as the required value in the given combination. Therefore, only the following six possible combinations remain to be considered:

No. of coins.	Value in cents.	No. of coins.	Value in cents
15	250	14	500
15	500	13	500
15	750	13	250

By the same line of reasoning I took up each of the above combinations separately, and from the 15 to 250 one derived a 10 to 50 combination in which only dimes, nickels and cents had not yet been considered—4 dimes, 1 nickel and 5 cents make such a combination. Working back through the proper combination, I found that I had used 5 cents, 1 nickel, 4 tens, 2 quarters, 3 fifties, 1 ($2.50), 1 ($5), 2 ($10), and 1 ($20).

Multiplying by 10 as determined in the second paragraph above, I summed up as follows:

50 cents . .	$0.50
10 nickels	50
40 tens	4.00
20 quarters . . .	5.00
30 fifties . . .	15.00
10 ($2.50)	25.00
10 ($5)	50.00
20 ($10)	200.00
10 ($20)	200.00
200 coins	$500.00

Teacher of Physics.

Snow Rollers

To the Editor of the SCIENTIFIC AMERICAN:

About a year ago I wrote you concerning some "Snow Rollers" which had formed on our lawn at Potsdam, N. Y. The article was published and caused a little comment at the time. I thought it might be of interest that the "rollers" have again made their appearance, in the same place, though in smaller numbers. It is a curious fact that in no previous year has this phenomenon been observed here, and now it has appeared twice in succession. T. J. MOON.

Middletown, N. Y.

The Salving of Submarines

To the Editor of the SCIENTIFIC AMERICAN:

The daily press records the sinking of a submarine of the navy of Great Britain; and the fact that no provision is or has thus far been made for supplies while a boat is submerged, leads me to suggest the idea that comes to my mind in connection.

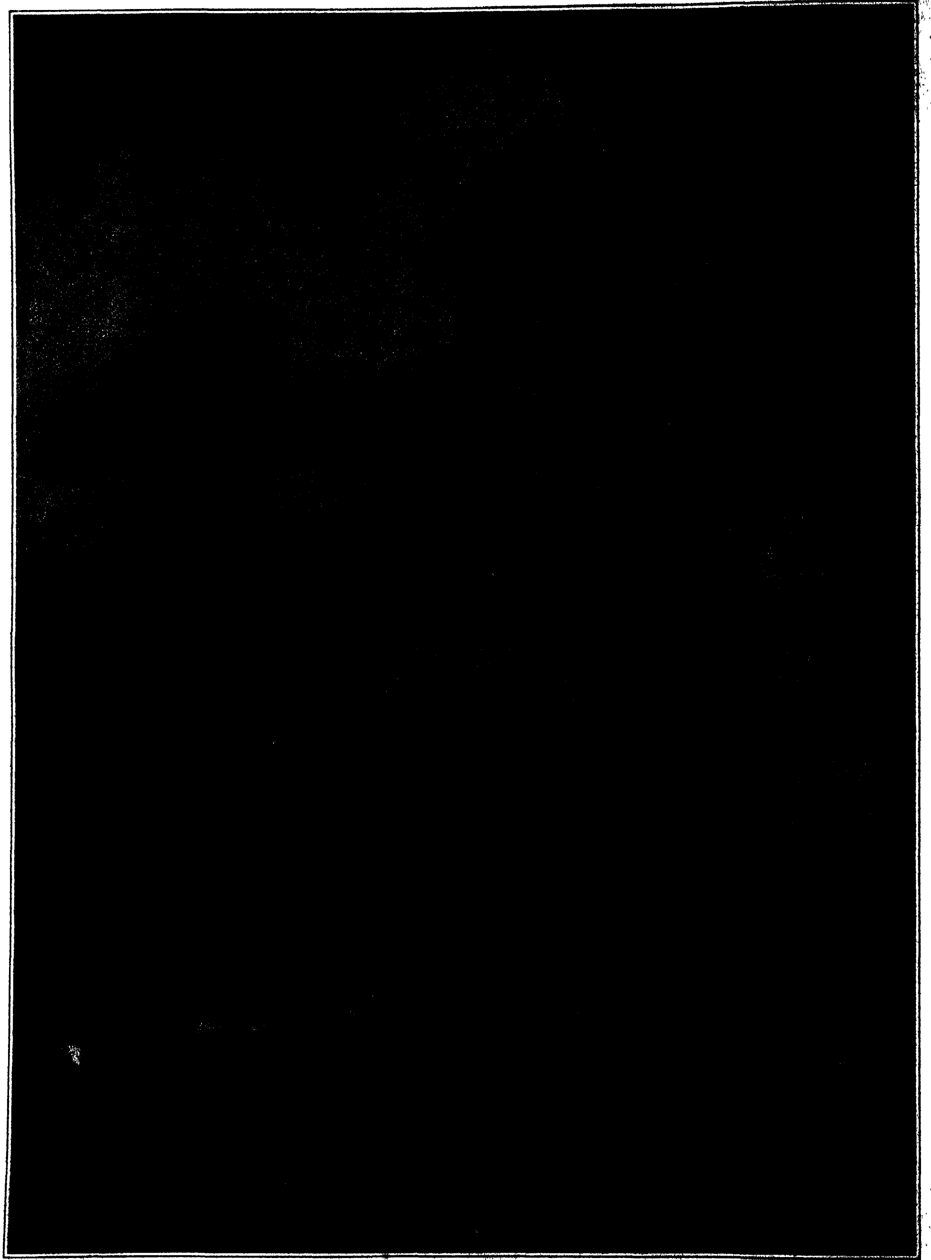
Were a length of hose contained in the submarine boat to pass through a hole in the top provided for the purpose, and the hose end connected with apparatus lighter than water, would it not be possible to—

1. Know the exact location of the submerged craft?
2. To keep the occupants imprisoned therein supplied with air and other necessities of life?

Then also if protruding hooks or bolts were fastened to the outside of the boat would it not be a provision that would tend to effect the raising of the structure submerged? ROLAND C. FINLEY.

Hamden, Conn.

Mr. Rodman Wanamaker of Philadelphia has decided to build a machine which will compete for the prize of $50,000 offered by Lord Northcliffe for the first crossing of the Atlantic Ocean in an aeroplane. The building of the machine will be intrusted to Mr. Glenn H. Curtiss, who has decided that the prize can be won in a flight of a single stage lasting not more than fifteen hours. The machine will have the general appearance here shown, and will be equipped with a motor of two hundred horse-power, which Mr. Curtiss is now testing.



General appearance of the Wanamaker-Curtiss biplane, in which an English and an American pilot will attempt to cross the Atlantic Ocean early during the present summer.

The Wanamaker-Curtiss Transatlantic Biplane

A VERY serious attempt is to be made during the season of the early summer to cross the Atlantic Ocean in a flying machine. Mr. Rodman Wanamaker of Philadelphia in a letter sent to the Aero Club of America, announces that he has commissioned Mr. Glenn H. Curtiss to construct a flying boat capable of making the trip across the Atlantic Ocean in a single flight of from twelve to fifteen hours.

So very little information has been given out as to the design of the aircraft in which this feat will be attempted that it is impossible to offer anything in the nature of critical comment. Mr. Curtiss has stated, however, that "for reasons not at all in accordance with those usually given for such a procedure a tractor screw in front of the machine will be used instead of the propeller usually seen in Curtiss flying boats." The hull will be of torpedo or streamline form of large diameter, almost entirely inclosed, so that in case of a forced "landing" in mid-ocean it can be relied upon to float for days. In the bow will be installed a motor of approximately 200 horse-power, readily accessible to the two operators. Twelve feet back of the motor will be the cockpit proper, and in it there will be room for the two men to sit down or move about. The controls will be in duplicate so that the machine may be handled by both men in unison, or by either one.

The wings will have a span of about eighty feet and the area of lifting surface will be about 1,200 square feet. The latest wings designed by Mr. Curtiss are able to rise from the water with a load of ten pounds to the square foot. Hence the actual lifting capacity of the Wanamaker transatlantic flying boat will be several tons, in other words sufficiently ample to provide for the enormous amount of fuel which must be carried. In outline the wings will be swept back at an angle of some six degrees. They will have a dihedral angle, rising from the center to the extremities to insure a certain amount of inherent stability.

Naturally everything hinges on the motor.

Up to the present time a 200 horse-power motor has not been mounted on a flying boat. To be sure Sikorsky has built four units of 100 horse-power each into his enormous machine. This, however, is not quite the same as concentrating 200 horse-power in the bow of a biplane. Even if the transatlantic flight proves a failure as a voyage, the experiment that Mr. Wanamaker is making deserves encouragement because for the first time light will be thrown upon the engine power required for large machines and on the behavior of very large engines in a regularly sustained flight.

The recent flight of Ingold, who covered a distance of about 1,000 miles in 16 hours, as well as the record flight of Victor Stöffler, who covered 1,340 miles in 24 hours, would seem to argue that given a perfect motor it is not utterly impossible to cross the Atlantic in 15 hours, in a single flight from dawn to dusk.

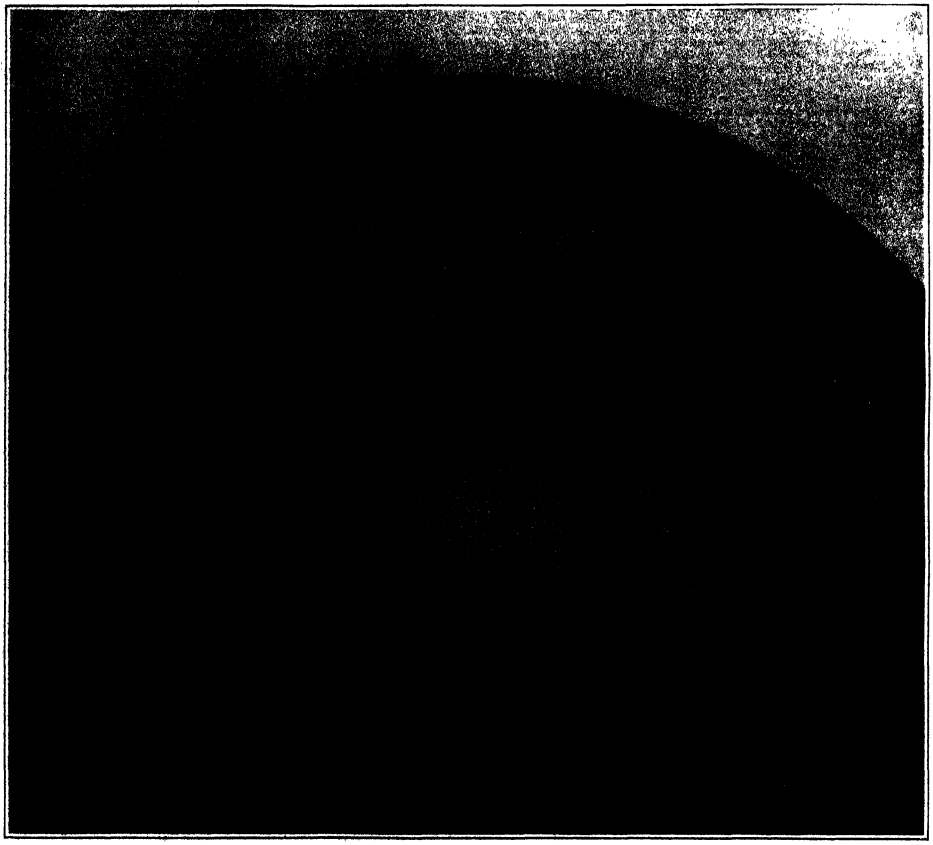
It may be questioned, however, whether Mr. Curtiss' expressed intention of having the machine fly at an altitude of 10,000 feet will be realized. The men who have made record altitudes testify to the difficulty of securing good motor compression at heights of 10,000 feet and over. Whatever may be the advantage to be gained by constant winds at that height, will be more than offset by imposing upon a brand new type of motor a difficulty with which even the tried engines of record breakers find it hard to cope.

Flying Around the World

THE ideal preliminary conditions of an aeroplane trip around the world such as the Panama Pacific Exposition authorities seek to encourage, include a thorough study of the portions of the proposed route not already aeronautically well known, the compilation of special maps and instructions, and, of course, the establishment of suitably equipped and provisioned landing places. It is passing strange that while the promoters of the race announce that a fund of $300,000 and possibly $500,000 (there is even talk of one million dollars) will be available for prizes, no provision appears to have been made for the equally important preliminary expenses of the undertaking.

It is impossible to estimate with any degree of accuracy what these preliminary expenses will be. Certainly there can be no haphazard start from San Francisco without a very careful plotting of the most desirable course. It may be that the aero clubs of the world will co-operate in mapping the routes for their own countries. But who will map out the routes over eastern Asia, the uninhabited islands that lie north of Japan, the bleak archipelago that spans the sea between Asia and North America, not to mention the all but unexplored wilderness in the heart of Alaska? The sum of $300,000 which has been set aside for prizes would in itself be hardly sufficient to meet the expenses of making the necessary preliminary explorations.

Consider also the necessity of landing places. How many shall there be? Assuming that the globe will be circumnavigated in stages of 600 miles there would have to be at least forty stations. By station we mean not merely a shed into which a machine can be run and housed for the night, but a depot for fuel and for the



One of the possible routes for circumnavigating the globe in a flying machine.

making of repairs. At least two men—skilled mechanics—must be assigned to each station. The cost of building the stations and of paying the salaries of the mechanics while they are on duty would amount easily to $1,500 for each station, in other words, $60,000. Add to this $50,000, the cost of building a machine strong and powerful enough to withstand the severe strain of such a tremendous trial (at least this much, it has been estimated, must be expended merely to cross the Atlantic) and the ambitious aviator must spend at least $410,000 in order to win a paltry $100,000 first prize

It is estimated that the distance which it would be necessary to cover would amount to about 22,000 miles. Assuming that the prize of $100,000 can be won, the successful aviator will have earned about $5 a mile. Mr. Grahame-White, whom Americans will remember as one of the participants in the Belmont Park meeting of 1910 as well as in flights at Boston in the same year and who, as many Americans can testify, knows how to charge for passenger flights, has stated in the press that his aviators at Hendon, England, are earning more than that per mile now

The time of ninety days allotted for the completion of the globe circuit seems extremely short in view of past performances. Vedrines consumed some weeks in accomplishing the 3,500-mile journey from Paris to the Pyramids Skillful aviator as he is, he flew on an average of only 100 miles a day. On the other hand, Brindejonc des Moulinais covered 3,002 miles in eight days in flying from Paris to Warsaw and St. Petersburg and back Vedrines' performance, however, is a more exact parallel to one of the stages in a globe circling flight He traveled over partly uncivilized countries, at great personal risk, whereas des Moulinais flew over civilized Europe after elaborate preparations had been made Yet successful as he was, Brindejonc des Moulinais is quoted as saying "The crossing of the Atlantic alone by any route or any system is impossible now, and probably will be for some time to come I doubt personally whether any pilot could stand the strain of a flight from Paris to New York even if he took his time about it"

In flying to Constantinople Vedrines was shot at by ignorant peasants. What would happen to an aviator who was compelled to land in the wilds of eastern Asia or on one of the sparsely populated Kurile Islands?

The art of aeronautical mapping has made much progress. The "international aeronautical chart," which will ultimately commensure the globe, is still in embryo, but plans for its construction have been matured by a committee of the International Aeronautic Federation. In the aeronautic charts of the Aero Club of France we already have an admirable model for the technical details of such publications. In the time available before the race it seems hardly possible to prepare special maps of the whole route. Where suitable *points de repère* do not already exist they must be erected.

Let us suppose, however, that the facilities at the command of the contestants, apart from the possession of larger aeroplanes and more powerful motors, and the presence of specially arranged landing and provisioning places at points where they are absolutely necessary, will not be superior to those enjoyed by Garros in his last trans-Mediterranean flight, or by Vedrines in his trip from Paris to Cairo What will be the special difficulties of a flight around the world? The mere distance—some 22,000 miles—is probably not one of them. In the last Michelin Cup contest Helen, a French pilot, made daily cross-country flights on 30 consecutive days, aggregating 10,000 miles. The conditions of this test forbade repairs to the motor or the renewal of any parts. Helen averaged 330 miles a day; but the "record" flight in 24 hours is Victor Stoffler's of 1,340 miles. These figures encourage the belief that the requirements of the 'round-the-world flight—22 000 miles to be made in 90 days—seem not unreasonable The race is planned for the months of May, June, and July At that season the contestants will enjoy the advantage of continuous daylight over a considerable part of their route North of about latitude 55 degrees there is no true night within a month or so of the summer solstice.

The length of the flights over water has been urged as the main difficulty. The longest lap of this character will be from southern Greenland to Iceland—say 670 miles With no fuss of preparation, and with a balky motor, Roland Garros recently flew 450 miles over the Mediterranean, from St Raphael to Bizerta Will not the aviators of 1914-15 better this record in the ordinary course of events?

So far we have ignored climatic and topographic conditions, and these we may now consider together. The question of temperature, in its effects on motors and men, is unimportant. It will be more a question of altitude than latitude in the coming contest, just as it is in the flights of everyday routine. An editorial on the race in the *New York Sun* probably reflects popular opinion in assuming that because Greenland and Iceland are included in the route the aviators will necessarily experience the rigors of a polar climate, but this is a fallacy. It is most misleading to compare Nansen's crossing of the Greenland ice-cap, as the editorial in question has done, with a momentary summer visit to Cape Farewell.

The general drift of the winds around the globe is decidedly favorable to the flight, which is to be from west to east, the direction of the great circumpolar whirl.

The journey from San Francisco across the American continent requires little comment. The aviators will naturally keep in touch with the Weather Bureau, in order to take advantage of the favorable and avoid the unfavorable, quadrants of cyclonic wind-systems. A crucial stage of the undertaking will be reached when the contestants set out from Belle Isle on the long flight to Greenland. Here the great—the almost insuperable—difficulty is fog. Statistics gathered at Belle Isle show an average of 10 days with fog in May, 17 in June, and 22 in July. Notwithstanding the fact that the notorious fogs of the Grand Banks lie to the south, the probability of foggy weather anywhere between Belle Isle and Cape Farewell during the summer months is very great. How this difficulty is to be solved, save by sheer luck, we are not prepared to suggest.

Ice is apt to be abundant off the coast of Cape Farewell, but the shore itself is free from ice and snow in summer and offers no serious obstacle to landing. The Eskimo population is extremely sparse, the nearest important settlement, Julianehaab, being 110 miles farther north. Presumably a regular landing station will be established at Cape Farewell, so that this consideration is unimportant.

The winds of the northern Atlantic Ocean are dominated by a quasi-permanent area of low barometric pressure—the so-called "Iceland low." The circulation around this "low," very active in winter, is comparatively sluggish in summer. The cyclonic storms which so frequently pass around the world from west to east in middle latitudes rarely run as far north as Greenland and Iceland, especially in summer. Local storms and squalls occur, but on the whole the wind conditions are not likely to prove a more dangerous feature of the Atlantic crossing than they would in a journey of similar length anywhere else in the world outside of the tropical and subtropical zones.

The next stage of the journey takes the aeronaut to Iceland. It fortunately happens that the west coast of Iceland is strikingly free from fog, owing to the fact that the ocean temperature in that region is always higher than the air temperature. At Stykkisholm there are only 6 days with fog in the year, on an average. On the eastern coast the conditions are reversed; Papey has 174 foggy days annually. Snow and ice rarely occur on the south and west coast in summers. The temperature sometimes rises at midday above 85 deg. Fahr., and the atmosphere is remarkably clear.

The next lap carries the aviator to the Hebrides and into the zone of occasional cyclonic storms. Fog occurs in the Hebrides one day in ten, and upward, during June. The journey through the British Isles to Paris, and thence to Berlin, Warsaw, St. Petersburg, and Moscow is all plain sailing—as aeroplane journeys go. The same may probably be said of the long stretch from Moscow to Vladivostok, where the trail is well blazed by the trans-Siberian Railway, and the climatic conditions are rather similar, except for somewhat cooler nights, to those that prevail in the interior of the United States in summer. The Urals and other mountains must be crossed, but such feats are now commonplace. The route is then across the sea to Korea, over the Japan Sea to Kobe, and thence northeastward by a truly formidable journey, *via* the Kurile Islands and Kamchatka, to Cape Deshenev (East Cape), and across Bering Strait to Alaska.

As soon as the Pacific seaboard of Asia is reached the aviator again encounters the fog problem, and this will haunt him more or less persistently until he reaches (if he ever does) the notoriously foggy bay of San Francisco. The entire coast of the Maritime Province of Siberia, including Kamchatka, is a region of dense and frequent fogs in summer, and the same is true of the Kurile Islands. Severe gales are said to be frequent in the Kuriles, but the fact is that very little is known about these islands, most of which have no permanent inhabitants and have never been explored. In Kamchatka the aviator has the alternatives of following a known coast-line, almost constantly shrouded in fog, or flying over a little-known interior, where there are no roads or settlements and a very sparse population of primitive inhabitants. The natural stopping-place in Kamchatka will be Petropavlovsk, the capital; a sleepy fur-trading village of 400 people. The region north of Kamchatka is even more desolate and forbidding. About the only saving grace of northeastern Asia from the aeronautical point of view is that the Russian government now maintains some powerful wireless telegraph stations in that quarter. All in all, the flight from Japan to Cape Deshenev appears to be the *crux* of the whole undertaking, and its feasibility in the present generation is certainly highly questionable.

A journey down the long Alaskan coast would again be attended by besetting fogs, varied with drenching rain-storms. These may, however, be avoided by flying well inland, where there are probably enough settlements and the country is sufficiently well mapped to make the trip feasible. The rest of the flight to San Francisco—after the stupendous feats that have gone before—may be taken for granted.

A $30,000 International Railroad Competition

UNDER a decree of the Ministry of Railroads, dated February 25th, 1913, the Chilean Government has called for an International Competition for Plans and Specifications for one central model workshop and four repair shops for the State Railways of Chile.

The bases of the contest are as follows:

1. A first prize of $20,000 for the best plan and a second prize of $10,000 for the next best. Honorary mentions will be awarded also. The money prizes shall be awarded only to plans for the central workshop.

2. The plans and specifications should be received at the Ministry of Railroads (Ministerio de Ferrocarriles, Santiago, Chile) not later than May 1st, 1914.

3. A Jury of Award composed of nine members appointed by the government and presided over by the Minister of Railroads, shall examine and pass upon the plans and specifications submitted, and report thereon within one month from the closing of the competition.

4. The prizes shall be paid within 30 days from the date of the jury's report.

5. The government of Chile reserves the right to reject any or all of the plans submitted, and consequently to withhold any or all of the prizes.

6. Plans and specifications to which prizes shall have been awarded shall become the property of the government, and all others are to be returned to their authors.

7. The fundamental requirements of the central workshop are as follows:

a. A capacity for repairing 500 locomotives with tenders per year, provided that no large repair work shall take more than from 60 to 90 days of eight and one half working hours. (An example of a large repair work would be the changing of cylinders and boilers, and their accessories.)

b. A capacity for the simultaneous and continuous repair of 50 passenger coaches and 400 freight cars.

(The present number of locomotives in operation is 600; of passenger cars, 500; and of freight cars, 6,000. These figures are to be increased yearly, as follows: Coaches and cars, 10 per cent; and locomotives, 5 per cent.)

c. It should be so equipped as to meet all the needs of the general service, its administrative organization, and the machinery and plants.

d. A capacity for producing not only the necessary pieces and parts, such as cylinders, boilers and mechanisms, but also such pieces as may be needed in the auxiliary repair shops.

e. Adequate stores for the stocking of reserve materials.

8. The central workshop may be presented in the plans as one plant to be built on a single site, or as two separate plants, one for locomotives and tenders, and the other for coaches and cars.

9. As to the auxiliary repair shops, their capacity or importance shall be determined by each competitor, taking as a basis the central workshop and bearing in mind the requirements of the service and traffic.

10. In drawing up these plans and specifications, the following facts should be taken into consideration;

a. That the necessary sites are to be furnished by the government without cost.

b. That native materials shall be used in so far as possible.

c. That prices of materials and machinery are to be estimated as placed on board at Valparaiso, and, therefore, not including customs duties.

d. That the State Railways will transport without charge all materials, but the cost of loading and unloading should be included in the estimates.

11. The government of Chile will furnish all available data and render all possible help for the drawing up of these plans and specifications, provided, however, that the competitor desiring such data or help shall have a duly authorized representative in Chile, who, on his behalf, shall express in writing his purpose to take part in the contest under these bases, and designate the persons who as experts are to undertake the studies in the country.

12. It is provided that this is exclusively a competition for plans and specifications, and that the government shall not incur any obligation as to the future construction of the works.

There are 36,500,000 young trees in the Government's forest nurseries.

An Organ on Which Color Compositions Are Played

The New Art of Color Music and Its Mechanism

By John W. N. Sullivan

In popular thought there is a well-marked line of demarcation between the Arts and the Sciences. But even a cursory examination reveals the fact that these two branches of human activity are in many cases closely connected. It is even true that some arts could not exist at all without the previous acquisition of a considerable body of scientific knowledge. The new art of kinematography is a case in point, and everyone is aware that the modern pianoforte is the result of a long development, a consequence of the increasing application of scientific principles to its construction. One of the most interesting examples of the reaction of Science upon Art is the new art of Color Music. In presenting this subject to the reader it is advisable to start with its analogy to Music, although, as we shall see, this analogy is not to be pushed to extremes. Both sound and color are vibratory phenomena, sound being due to vibrations of the air, and color to vibrations of the ether. Two notes of different pitch correspond to different rates of vibration, the higher note corresponding to a faster rate of vibration in such a way that doubling the rate of vibration raises the pitch of the note by an octave. The basis of the musical scale is the octave. Now if we examine light rays of different colors we should find that their rates of vibration are different. The light rays which correspond to the color violet are vibrating at almost twice the rate of the light rays corresponding to the color red. Color in light is analogous to pitch and sound. In the spectrum, which we obtain by decomposing white light by means of a prism, the colors range from red at one end to violet at the other, the intermediate colors corresponding to intermediate rates of vibration. It cannot fail to strike the reader that we have here a close analogy with the musical octave. On this basis we may found an explanation of the fact that certain combinations of colors are regarded as harmonious, whereas other combinations produce an intolerable sense of discord. So far we are on familiar ground. We are dealing with the statics of the subject, as it were. But while combinations of sounds are analogous to combinations of color, a musical composition is differentiated from a painting by the introduction of the time element. Music possesses the additional element of rhythm. It is Prof. Rimington's chief claim to distinction in this connection that he has imported this element also into color, thus giving rise to a new and beautiful art, the art of Mobile Color or Color Music.

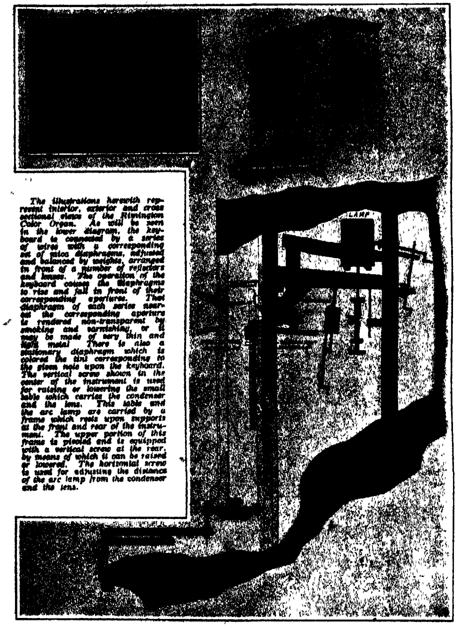
Rimington bases his work in this subject upon two indisputable psychological facts: Firstly, different successions of color, different color sequences, give rise to different sensations in the observer; and secondly, the rhythmic succession of these colors is of as much importance as the rhythmic succession of notes in a musical composition. Undoubtedly the best way of enabling the reader to realize the truth of these assertions would be to enable him to be present at the performance of a color composition; but as that is at present impossible, we must have recourse to describing a color composition in words. We cannot do better than quote from Prof. Rimington's book "Colour Music."

"Imagine a darkened concert-room. At one end there is a large screen of white drapery in folds surrounded with black and framed by two bands of pure white light. Upon this we will suppose, as an example of a simple colour composition, that there appears the faintest possible flush of rose colour, which very gradually fades away while we are enjoying its purity and subtlety of tint, and we return to darkness. Then, with an interval, it is repeated in three successive phases, the last of which is stronger and more prolonged.

"While it is still lingering upon the screen a rapid series of touches of pale lavender notes of colour begin to flit across it, gradually strengthening into deep violet. This again becomes shot with amethyst, and afterward, changing gradually into a broken tint of ruby, gives a return to the warmer tones of the opening passage.

"A delicate primrose now appears, and with little runs and flushes the pulsation leads through several passages of indescribable cinnamon colour to deep topaz. Then suddenly interweavings of strange green and peacock blue, with now and then a touch of pure white, make us seem to feel the tremulousness of the Mediterranean on a breezy day, and as the colour deepens there are harmonies of violet and blue-green which recall its waves under a Tramontana sky. More and more powerful they grow, and the eye revels in the depth and magnificence of the colour as the executant strikes chord after chord amongst the bass notes of the instrument.

"Then suddenly the screen is again dark, and there is only a rhythmic and echoing beat of the dying colour from time to time upon it. At last this disappears also, and there is another silent pause, then one hesitating tint of faded rose as at the opening of the composition.



The illustrations herewith represent interior, exterior and cross sectional views of the Rimington Color Organ. As will be seen in the lower diagram, the keyboard is connected by a series of wires with a corresponding set of mica diaphragms, adjusted and balanced by weights, arranged in front of a number of reflectors and lenses. The operation of the keyboard causes the diaphragms to rise and fall in front of their corresponding apertures. That diaphragm of each series nearest the corresponding aperture is rendered non-transparent by smoking and varnishing, or it may be made of very thin and light metal. There is also a stationary diaphragm which is colored the tint corresponding to the given note upon the keyboard. The vertical screw shown in the center of the instrument is used for raising or lowering the small table which carries the condenser and the lens. This table and the arc lamp are carried by a frame which rests upon supports at the front and rear of the instrument. The upper portion of this frame is pivoted and is equipped with a vertical screw at the rear, by means of which it can be raised or lowered. The horizontal screw is used for adjusting the distance of the arc lamp from the condenser and the lens.

Apparatus with which the "music" of color is produced.

"Upon this follows a stronger return of the colour, and as the screen once more begins to glow with note after note of red and scarlet, we are prepared for the rapid crescendo which finally leads up to a series of staccato and forte chords of pure crimson which almost startle us with the force of their colour before they die away into blackness."

This description may serve to show the imaginative reader that the new art is capable of producing considerable emotional effect. The possibility of the new art had occurred to several people before Prof. Rimington undertook his experiments, but it is a far cry from mere possibility to the actual perfecting of an instrument which should turn the possibility to an actuality. The apparatus which has transformed the art of color music from a dream to a reality is called by Prof. Rimington a "Color Organ," and consists essentially of three parts.

We have firstly, the source of light; secondly, the prisms and lenses for splitting the light into a spectrum; and thirdly, the mechanism which enables the performer to project given colors on the screen for a given time. One of the chief difficulties attending the construction of the instrument was found in securing efficient sources of light. Rimington employs naked arc lights, having a total candle power of about thirteen thousand. A well-known difficulty attending the construction of all arc lamps is to insure absolute steadiness of the arc. At one step in overcoming this difficulty, the Professor was led to invent a new form of carbon holder, which consists of a fireclay receptacle with three prongs, and has proved itself distinctly satisfactory. Nevertheless, a slight unsteadiness remains, and future experiments are going to be conducted with a metallic filament lamp. The mercury vapor lamp, in other respects very satisfactory, labors under the disadvantage that the red is almost entirely absent from its spectrum. The prisms are bi-sulphide of carbon prisms and the lenses are of the usual type. It is in the controlling mechanism that the resemblance to an ordinary sound organ becomes prominent. We have a keyboard which is exactly similar to the keyboard of an ordinary organ. Depressing a key enables a current of compressed air to reach the valve of a small motor, which motor in turn drags down a diaphragm, thus permitting light of a color dependent upon the key struck to flood the screen. Instead of one diaphragm a number of diaphragms are used, thus enabling the intensity of the projected color to be regulated. A complete spectrum corresponds to each octave on the keyboard, and the striking of the two notes of an octave simultaneously, for instance, removes two diaphragms from the path of the light. The diaphragms are each carefully colored to the precise shade of that part of the spectrum that they normally intercept. By a further device the whole keyboard may be made to correspond to the range of the spectrum, but this is chiefly useful in improvising. An ingenious modification has been the introduction of an auxiliary diaphragm of mica, crossed by lines which crowd closer together as they approach one side The light is therefore split up more at one side of the diaphragm than the other, and as the diaphragm is gradually removed from the light path, the light gradually grows in intensity. This prevents the light flooding the screen with disagreeable abruptness. The whole mechanism is really remarkably simple from the engineering point of view, although effects of considerable complexity can be produced by it. The compressed air is supplied by a bellows as in an ordinary organ.

Prof. Rimington is of the opinion that it is in combination with music that the new art will find its chief development. The close association of colors with sounds has always been noticed by musicians. In some works on music the writer has gone so far as to give a list of colors corresponding to the timbre of the various instruments in an orchestra To most people there is a distinct connection, which only requires to be pointed out. Thus Lavignac in his book "Music and Musicians," likens the timbre of an oboe to a rustic green, and the blast of a trombone to a heavy crimson. But this correspondence must not be made to assume an undue importance. While most people are agreed that certain instruments recall certain colors more vividly than others, there is no great unanimity of opinion respecting the colors chosen as belonging to certain instruments. But in its main lines the analogy holds good. Everyone would admit that a gradual fading from a bright to a dull color corresponds to a pathetic phrase in a musical composition. And vivid, striking colors do seem to correspond to the more vivid striking instruments of an orchestra. On this basis Prof. Rimington has devised color compositions illustrative of musical compositions, and the performance of the two together has been attended by the most satisfactory results. In writing a color composition musical terminology is employed, with the usual time markings and marks of expression. It appears that while most people find pleasure in a color composition done in slow time, rapid color passages require an educated eye. After a certain amount of training, however, rapid color passages are capable of furnishing a

(Concluded on page 170.)

A Million Shot Group

PROBABLY the first million shot group that has ever had its picture taken is shown herewith.

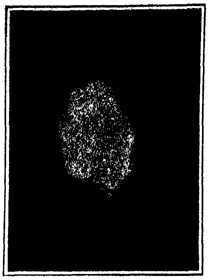
Speaking generally, most of us are content to regard a group of 10 hits, or may be two or three groups of 10 hits, as affording sufficient testimony of the accuracy or otherwise of a cartridge; it is something out of the ordinary therefore to get a single group of so many thousands of shots that if we call it a million we shall not be straining the truth overmuch

The illustration depicts such a group made with the 0.22 rim fire long rifle cartridge used in a target rifle at 100 yards

In the daily routine tests at a well known cartridge works in Bridgeport, a quantity of the cartridges are taken promiscuously from each loading machine every hour and mixed. Ten groups of 10 hits are then made from the machine rest at 100 yards, and these groups must conform to the required standard of accuracy or the batch is condemned The ten targets are mounted in a revolving frame which turns one tenth of a revolution for each shot and brings each target alternately in front of the gun and opposite precisely the same spot on the stop butt behind, consequently the group made on the stop butt is a composite of all the groups on all the targets.

Our illustration is from a photograph (five eighths actual size) of the piece of the stop butt behind the targets, which, though of ½-inch steel, is completely perforated and had recently to be replaced.

How closely the accuracy standard is maintained is clearly shown. The central hole, which oviously includes the majority of the hits, measures 2 inches by 1.4 inches —practically within the circumference of a silver dollar—while the thickly dented halo round it which embraces the remainder of the hits is just about 3 inches in diameter The tendency of the group toward an oblong shape clearly indicates the normal grouping



A hole that bears witness to accuracy in cartridges.

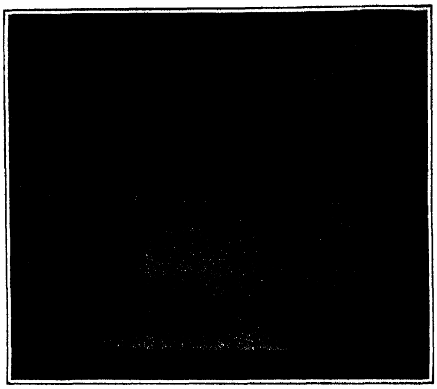
Curious Cloud Formation

WERE it not for the clew of the trees silhouetted against the sky, one would be apt to turn the accompanying picture upside down and regard it as a field of broken ice instead of an excellent example of *Cirro-cumulus* clouds or what is commonly known as "mackerel sky."

We are indebted to Mr. Frederick M. Smith, of La Mesa, California, for the photograph. He writes:

"On the 17th of September a cloud formation passed over this place which was of such peculiar appearance that it tempted me to make a record of it. The field of clouds spread over an area of perhaps two and one half miles square. I have seen at different times this same formation, but not so strikingly displayed as it was on this occasion."

For the purpose of comparison we publish under the cloud picture a photograph of a field of ice The picture was taken in Toronto Bay. If strong sunlight were reflected from the ice, the resemblance would be much more striking

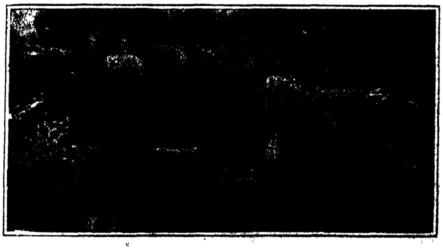


Curious "mackerel sky" formation that resembles a field of broken ice.

A field of ice in Toronto Bay. Compare with the picture above.

The Motor-car Express

A NOVEL form of passenger service is to be found in California A narrow gage railroad runs from Caldor to Diamond Springs, and to provide quick transportation over this line an automobile has been pressed into service The wheels have been removed and car wheels substituted The rear wheels are chain driven. The forward part of the vehicle is mounted on a four-wheel swivel truck. Of course the engineer or chauffeur does not attempt to steer the vehicle The automobile is a 1907 model, but apparently it is still in good running condition It is scheduled to make the round trip between Caldor and Diamond Springs (70 miles) in two hours and a half.



Motor car passenger service on a narrow gage railroad.

Motorcycle Electric Lighting Outfit

THE elimination of oil and acetylene gas lamps from motorcycles grows apace; manufacturers slowly but surely are turning to electricity as an illuminant, a fact which is amply reflected by the new machines that are being placed on the market against the new season. Among the various dynamo lighting systems which have appeared within a comparatively short time, the one which is illustrated herewith has a number of individual characteristics which make it interesting and which should make it appeal to those who incline to side-step all complicated mechanisms.

As the picture shows, the outfit consists of nothing more than a tiny little dynamo which is clamped to the front fork of the machine and driven by frictional contact with the tire, and a reflector containing an incandescent bulb.

The construction of the dynamo is unusual. The field consists of a large bell-shaped magnet of the permanent type to which the aluminium casing is attached. The armature shaft is carried in ball bearings, both of which are between the armature and the driving wheel. The armature winding consists of a sufficient number of turns of fine wire to insure the generation of six volts when the speed of the motorcycle becomes about 25 miles an hour. As there is no commutator, it is evident that the current is alternating and hence that a storage battery cannot be used with the generator. To provide a source of energy for the lamp when the motorcycle is not running a few cells of dry battery may be used.

In the electrical connections, one end of the armature winding is simply grounded to the armature shaft. The other end is connected to a wire gauze brush which bears against a button on the end of the armature shaft. But one wire is needed between the generator and the lamp, the ground connection serving for the return. The weight of the generator is only two pounds.

Motorcycle headlight and electric generator.

A Quick-acting Thermo-pile

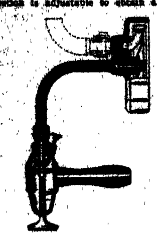
ORDINARY thermo-piles are rather slow-acting instruments. In their original form, as suggested by Melloni, they are made up of a number of metal rods joined in a batch, at the outer ends of which there are the two rows of soldered joints. On account of the great heat capacity of such a system, any increase in the temperature of the joints exposed to heat radiation is bound to last a long time, temperature equilibrium being reached very slowly.

In a paper recently read before the Amsterdam Academy of Sciences, J. H. Moll describes a new type of thermo-pile made up of a large number of small metal strips consisting partly of constantan and partly of copper, and which at their two outer ends are soldered to two copper terminals. The constantan-copper strips may be in their entirety exposed to the radiation, when on account of the very considerable difference in heat capacity of the two joints, the central joint is raised to a higher temperature than the outer one. However, mainly by reason of the excellent heat conduction between the two joints, these, after a very short time, will reach temperature equilibrium. Since the two metals have very different coefficients of heat conduction, their thickness and length should be chosen at such a ratio that during heat radiation the temperature in the central joint is highest.

Such elements are most readily combined into thermo-piles. One of those constructed by Moll comprises 80 elements which, arranged in 3 rows, filled up nearly completely a circle 2 centimeters in diameter and possess a total resistance of about 9 ohms. The sensitiveness and absence of inertia are strikingly shown by the fact that the light from a standard candle, at 1 millimeter's distance, will set up in it a thermo-force of 18 microvolts, the thermo-current reaching within 1¼ seconds, 99 per cent of its definite figure.

[illegible] particularly the design is for the [illegible] of a machine especially adapted for the [illegible] of [illegible] on [illegible] [illegible].

MASSAGE VIBRATOR.—G. A. [illegible], 67 Bay [illegible] St., Brooklyn, N. Y. This invention relates to a massage vibrator of that type in which the oscillatory element is driven from a motor through a flexible shaft, the motor being of the water turbine type. It provides an effective connection between the oscillatory element and rotary shaft of the device, which connection is adjustable to obtain a light or heavy vibratory action. By the provision of an improved mounting a rapid movement of the vibrator is insured. A form of motor of high efficiency is provided propelled by water taken from an ordinary city service pipe.



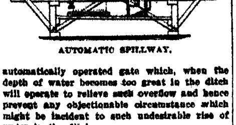
MASSAGE VIBRATOR.

STARTING AND STOPPING DEVICE FOR PHONOGRAPHS.—F. E. HARR, 612 W. King St., Martinsburg, W. Va. The purpose here is to provide a starting and stopping device for phonographs and such machines and arranged to enable the user of the machine to readily start the same and to permit of conveniently and quickly setting the device according to the record with a view to automatically stop the machine at the time the stylus reaches the end of the groove in the record.

GROOVING MACHINE.—J. J. MARSTALL, care of Marstall Furniture Co., Henderson, Ky. This improvement has reference to wood-working machines, and its object is to provide a new and improved machine more especially designed for simultaneously forming pairs of diverging grooves in two boards or other pieces of stock.

AUTOMATIC VENDING AND CHANGE MAKING MACHINE.—E. E. HENRY, 214 9th St., Astoria, Ore. This machine delivers merchandise, but is more particularly designed for a ticket-vending and money-changing machine in which coins of different denominations may be inserted, and change delivered to the value of the inserted coin, or in which coins or equivalent checks of varying value may be inserted and tickets and change be delivered to the value of the said coin or other check.

AUTOMATIC SPILLWAY.—C. SCHALLES, Cortez, Colo. The invention relates to artificial water courses, such as flumes, irrigation ditches or the like. Among the objects of the invention is to provide a ditch having an automatically operated gate which, when the depth of water becomes too great in the ditch will operate to relieve such overflow and hence prevent any objectionable circumstance which might be incident to such undesirable rise of water in the ditch.



AUTOMATIC SPILLWAY.

POST COLLAR FOR ROCK DRILLS.—R. NEWELL, care of J. F. Hambitzer, Houghton, Mich. This invention relates to the collars sometimes termed safety clamps, used on drill columns or posts below the drill, or below the column arm if the latter be employed. The object is to produce a collar which may be quickly and effectively adjusted in position and instantly loosened when required.

CONCRETE MIXING MACHINE.—R. L. CAIRNS, care of Speed Mach. Co., 70 Erie St., Passaic, N. J. The object here is to provide a machine of the revolving type which may be used as a "continuous type" so-called, for mixing the concrete in predetermined quantities, or in a continuous stream, as may be desired.

WASHING MACHINE.—P. W[illegible], care of H. [illegible], [illegible] W. 20th St., New York, N. Y. The invention provides a supporting frame for a machine readily adjustable to tubs of various sizes and shapes, provides a swinging frame which may be readily lifted out of the way when placing in or removing from the tub the clothes to be washed.

[illegible] MACHINE.—J. DeC. HALL, [illegible] [illegible]

[illegible] mechanical canceling, or indorsing of checks in banks or other institutions where the large amount of such work necessary entails considerable time when done by hand.

GEOGRAPHIC POSITION INDICATOR.—F. R. SWEENEY, 2183 15th St., Troy, N. Y. This improvement provides for automatically and at all times indicating the position in degrees of latitude and longitude of a moving body; provides a plurality of members, one thereof being maintained parallel to the earth's polar axis and the other of said members being maintained fixed in space without reference to the earth's surface; and provides the members mentioned with indices adapted to show the variation of the plumb levels at all points on the earth's surface.

MOTOR KNIFE GRINDER.—A. P. REDDEN, 10 Clifton St., Worcester, Mass. This improvement has reference to machines for grinding wood-working tools, and has particular reference to a machine adapted to be operated especially by electric motor, and is therefore portable so as to be moved in any suitable position in a work-shop or mill.

AIR PUMP LUBRICATOR.—G. M. SCHWEND, Birmingham, Alabama. Mr. Schwend's invention is an improvement in air pump lubricators, and has for its object the provision of mechanism for use with air pumps, wherein means is provided for throwing a charge of oil and water into the cylinder of the pump operated by the action of the pump.

Prime Movers and Their Accessories.

MULTIPLE POWER ENGINE.—W. S. WALKER, Lillydale, Monroe Co., W. Va. In this case use is made of high pressure cylinders, connected pistons in each pair of cylinders, steam chests for each pair of cylinders and connected by sets of admission and exhaust ports with the ends of the corresponding cylinders, valves in the said steam chests and controlling the ports, the exhaust motive agent from one end of a high pressure cylinder passing partly into the other end of the same cylinder and partly into one of the low pressure cylinders, and the exhaust motive agent in one low pressure cylinder being used expansively in the other, the pistons in the low pressure cylinders reciprocating at double the speed of those in the high pressure cylinders.

DAMPING TORSIONAL VIBRATIONS IN CRANK SHAFTS.—F. W. LANCHESTER, 53 Hagley Road, Edgbaston, Birmingham, England. The invention relates to high-speed reciprocating engines, and more especially to an improved method of and apparatus for eliminating certain forms of vibration in the running of high speed multicylinder engines, such as the four and six-cylinder internal combustion engines used for the propulsion of motor vehicles.

EXPLOSIVE ENGINE.—D. M. TULLOCH, 180 Pearl St., New York, N. Y. This invention more particularly is directed to an engine having an improved means of control of intake and exhaust. The principal design is to provide a mechanism for controlling the intake and exhaust of cylinder gases, the said mechanism being positively actuated by the reciprocating piston.

TEST OR PRIMING COCK.—B. MORGAN, Tews Court, Newport, R. I. The invention refers more particularly to a device which comprises a cylinder plug and a closing plug movably associated with the cylinder plug, the cylinder plug affording means for the introduction of an explosive fluid into the cylinder upon which the device is mounted, and having a valve-seat, the closing plug having a self-centering valve-seat-engaging part adapted to close the cylinder plug

Railways and Their Accessories.

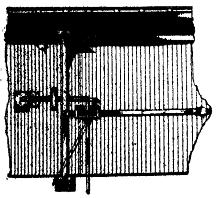
ADJUSTABLE TIE-PLATE.—J. ODIEN, 49 Ashton Place, Buffalo, N. Y. In the present patent the invention has reference to tie-plates for railways, and the object thereof is the provision of a strong and inexpensive plate which will accommodate rails of different sizes and which will prevent lateral movement of the rails positioned thereon.

RAILWAY SWITCH.—J. W. HUBBARD, Eau Claire, Wis. The purpose here is to provide a construction of locking device for railway switches which will operate more readily and advantageously than the apparatus set forth in this inventor's application for a patent, Serial Number 660,257, and to this end he provides his improvements with suitable antifrictional braces to engage the side of a draw bar and afford the desired results.

SELF LOCKING SPIKE.—G. I. DE FORCE and MOSES [illegible]. Address the latter, 506 State St., Erie, Pa. This invention comprehends a spike having all the advantages of an ordinary spike, and at the same time provided with shoulders of peculiar form for preventing the ready withdrawal of the spike from the wooden cross tie or other analogous member into which the spike is driven.

CAR COUPLING.—[illegible] L. ROBERTS and [illegible] L. [illegible], [illegible] W. Front Ave., Ashland, Ky. This invention relates to railway draft appliances and has particular reference to car couplers of the Janney type. The improvement provides for a number of structural features of advantage in the detachable yoke member constituting the main part of the device, whereby the same is strengthened and otherwise made more suitable in practice.

CAR DOOR OPENER.—J. W. CARVER, Hay Springs, Neb. The invention relates to an apparatus adapted to be installed on grain or box cars for affording convenient means for opening and closing the slide door of such cars. The invention provides a stationary frame applied to the body of the box car and including a track along which moves a carriage that is operatively connected with the doors, said carriage being moved step by step in one direction by a novel mechanism to open the door and in the opposite direction to close it.

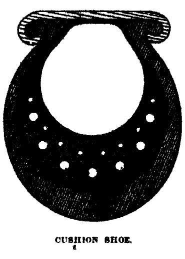


CAR DOOR OPENER.

MACHINE FOR GROOVING RAILWAY SLEEPERS.—A. PANKL, Kommanditgesellschaft Guido Rütgers, Vienna, Austria-Hungary. In machines for cutting into the upper surface of the sleeper receiving the tie plate, the ends of the sleeper are yieldingly pressed against fixed guide rails near the rotary cutters and then pushed past the latter, whereby such grooves of desired width are cut in the predetermined position and whatever may be the thickness of the blank or its transverse sectional shape. But if the upper surface of the raw sleeper is not plane for any reason, then the groove may become too deep or too shallow, the sleeper is either too much weakened by the groove or the groove is too shallow for the purpose. The inventor overcomes this difficulty.

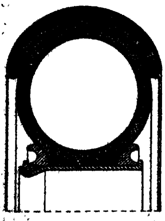
Pertaining to Vehicles.

SHOE.—R. D. S BENNETT, 514 West Mt. Vernon St., Springfield, Mo. This invention relates to tires and parts associated therewith, the more particular purpose being to provide an *improved form of cushion shoe forming* practically a part of the tire and adapted for maintaining the firmness thereof while permitting a considerable degree of resilience in the tire. It further relates to improvements in shoes or cushions forming parts of tires and carried thereby for the purpose of increasing the general efficiency of such structures.



CUSHION SHOE.

PNEUMATIC PUNCTURE PROOF TIRE.—F. NEWBAUER, Valley City, N. D. In this patent the invention relates to pneumatic tires for use on automobiles, and includes a novel, detachable, puncture proof tread, as well as a tire extending continuously in closed form at the inner side, whereby the inner tube is effectively protected against possible damage by defective wheel rims. The accompanying engraving shows in cross section a tire embodying the invention.



PNEUMATIC PUNCTURE PROOF TIRE.

AUTOMOBILE SLEIGH.—W. J. WRIGHT and R. H. HOCKIN, Oak Lake, Manitoba, Canada. This attachment is for use in connection with automobiles and other motor vehicles for the purpose of propelling such vehicles through the snow and it comprises an arrangement of parts upon which the body of an automobile or other motor vehicle can be easily and readily mounted when road conditions are such as to make the ordinary apparatus of the motor vehicles of little or no utility

VEHICLE STEERING DEVICE—F. S HARRIS, Waverly, Ill For the purpose of this invention, use is made of brackets attached to the axle and steering rod members pivoted on the brackets and having a sliding connection with each other, and a single spring engaged at its ends by the said members to compress the spring on shifting the steering rod sidewise in either direction

SNOW PLOW—W L. STADIG, Soldier Pond, Maine An object here is to provide a machine so mounted on sleds as to accommodate itself to uneven roads; to provide for convenient adjustment of the snow removing devices to the end that a wider or narrower way may be cleared, and the snow removed to produce an essentially level way, or to leave a ridge or cone at the center.

VEHICLE WHEEL.—G R. WILLIAMS, 620 Empire Bldg., Atlanta, Ga The invention relates to resilient wheels, and provides a structure presenting advantages over what is described and claimed in Letters Patent No 921,498 granted to Mr. Williams. The principal object of the present patent is to provide a wheel, characterised by an arrangement of parts in which the spokes of the wheel are in a condition of initial stress.

VEHICLE FENDER—G. HIPWOOD and P. EGAN, 39 Cortland St., New York, N Y This invention provides an apparatus adapted to operate in dual capacity, as a buffer and a fender; provides means for causing the apparatus to automatically assume a position to operate in the latter capacity, and provides means manually operative for disposing the mechanism in position to operate in either of the capacities mentioned, and if desired without necessitating the chauffeur or driver leaving the vehicle.

SHOCK ABSORBER.—J M. JACKSON, Parkersburg, W. Va The invention refers to shock absorbers for vehicles, and the primary object is to provide an arrangement in which, under normal road conditions, there is no engagement of any parts and therefore no noise and no necessity for lubrication

SPRING WHEEL—D. A. GRAY, Chattanooga, Tenn. An object of this inventor is to provide a device which will have the advantages of a pneumatic tire, but which will not subject the owner of the vehicle to the delays incident to punctures and blow-outs such as occur with pneumatic tires.

Designs.

DESIGN FOR A CRACKER OR LIKE ARTICLE—H HANDY, 240 W 104th St, New York, N. Y. In this ornamental design for a cracker or like article, the design shows a figure of a man of the old peasant type in a characteristic and picturesque posture.

CARPET OR RUG—J F DU BOIS, Springfield, Mass, care of G S. Squire, 25 Madison Ave., New York, N Y In this design for carpet or rug the fine effect is produced by an ornamental border inclosing a field of closely clustered figures without a centerpiece

DESIGN FOR RUBBER MAT BINDING.—F. H TIMKE, care of John Kroder and Henry Reubel Co., 107 E 17th St., New York, N. Y This design for rubber mat binding shows a binding of very simple, but attractive features of ornamentation.

DESIGN FOR A BATHING CAP.—R PARKER, care of Parker, Stearns & Co., 300 Sheffield Ave, Brooklyn, N Y The first figure in this ornamental design shows a perspective view of a bathing cap, the adjusting ribbon being shown in an untied fashion, while the second is similar to the first, but showing the ribbon drawn and tied.

DESIGN FOR A WINDOW DISPLAY.—C E. ISACKE, 96 Fifth Ave, Manhattan, N Y, N Y In this ornamental design for a window display the figure shows a front perspective view of an attractive structure.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

WE wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialised, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

MUNN & CO.,
Patent Solicitors,
361 Broadway,
New York, N. Y.

Branch Office:
625 F Street, N. W.,
Washington, D. C.

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12935) E. R. R. asks: If a passenger train of all-steel cars and running in the electric zone should be derailed and make contact with the third rail or the overhead wire should be torn down and come in contact with the cars, what effect would it have on the passengers? Is there a chance that in such an accident, the loss of life would be greater than any we have had with wooden cars or when heated by stoves? A We do not think that the injury to passengers in a steel car would be any greater upon derailment, or other contact between the car and the third rail or trolley wire, than with a wooden car, if as great The current would find an easy path over the exterior of the car to earth, and unless in some unusual circumstances should not enter the interior of the car at all The bodies of the passengers would present so high a resistance that no injury should ordinarily result. Doubtless many nervous people would suffer from shock in such a case, but the shock would not be electric However, no one can prophesy with any positiveness about this matter Each case would have its own peculiar conditions and results

(12936) H. C. K. asks: 1. Is there any truth in the disputed arguments among mechanics and engineers that a long screw driver will drive a screw easier than a short one if the handles are exactly the same? A All mechanics find it easier to drive a screw with a long screw driver, or think they do. It is quite possible that the long handle is more easily kept in a right line with the screw, and thus aids in the work We do not think the discussion a very important one. 2. Does it change the location of the poles on the surface of the earth if you change the inclination of the axis of the earth? A The axis of the earth is all the time moving in the earth, and the latitude of places is changing a very little This you will find in Todd's "New Astronomy," which we send for $1 45 postpaid

(12937) Mr. N. R. Crawford sends us the following formula for sugar-curing of meat, and we take pleasure in giving our readers the benefit of this advice: For 1,000 pounds of pork, take 30 pounds of pulverized salt, 5 pounds sugar, 1 pound black pepper, pulverized, and 1 ounce of saltpeter. Mix the above together. While the pork is hot, cut it up and rub the mixture thoroughly over the meat, rubbing it in all crevices. Lay it on a table or shelf and leave three days, after which go over and resalt again as the first time In three days more go over it the third time Allow it to stay spread about one week or ten days, and hang it up and smoke it. The above amount of salt, sugar and pepper will be sufficient to salt the 1,000 pounds the three times. The quality of the meat will be much improved over the old method The first application must be applied while the animal heat is in the meat

(12938) G. A. C. writes, referring to Query 12879, that we may possibly see a distant star by the light which is reflected from the surface of the earth *to our eyes* and *thus increased* much above what the star can send in a direct line to the eye, also that we see an object when we look at it by some power of the eye by which we do not have to wait for the light to come to us, but see instantly by the act of turning our eyes in the direction of the object, that thus a "tele-microscope" might be invented which would not simply penetrate space instantly, but disclose minute structures instantly in the most remote regions of space. We are not able to agree with this explanation of the mode in which we see a distant heavenly body, and may briefly point out the differences in our view of the matter. 1 It does not seem possible that we see a heavenly body by light which has been reflected from the earth, since we should then see the light coming up to us from the earth, and not down from the sky We see an object in the last direction followed by the light from that body as it enters the eye 2 Nor do we see an event in our field of vision at the instant it occurs, but only after the light which communicates the knowledge of the event to us has traversed the space between our eye and the place where the event occurred Prof Simon Newcomb set a mirror at Fort Meyer and sent light from the foot of the Washington Monument to Fort Meyer on the other side of the Potomac, and measured the time which the light required to go over that space and return This is described fully in our Supplement No 557, price ten cents. This being the case, Prof. Newcomb could not have seen the light till it had traveled over that space twice It would have been the same if he had sent his light to the moon and back, or to a remote star 3 There is an error in most people's minds as to what is meant by looking at anything. Some people seem to think that we do something with the eyes in looking Nothing of the sort To look at a thing simply means that we turn the eye so that light from that thing can enter it and thus enable us to see what that light can convey to the mind We see what was happening there when the light left its source. 4 The idea of a "tele-microscope" is very old In the early days of the New York *Herald* it published the famous "Lunar Hoax," which was that a combination of a microscope and telescope had been made in England so that the image of the moon could be studied and the minutest details of its surface and inhabitants could be seen. It is not necessary to say that the hoax was short lived. The arrival of the first vessel from England exploded the story and revealed the hoax. No telescope can reveal minute details or annihilate space and time. In darting glances at some near object there is nothing sent from the eyes of the darter to the near object, unless it be an electric shock, or magnetic impulse, and these require time to travel.

(12939) D. L. M. asks: From the time of my childhood up to the present time I have heard the statement made and reiterated many, many times, that the earth is constantly cooling, and that the time will come when the earth will be a frozen body. Last Summer I heard a minister make the statement in a sermon. At once my mind nailed the absurdity (if it be such), for thermal or heat rays will not pass through a vacuum, but, on the other hand, we know that light rays readily do. Now from this you can readily see that the heat coming to us from the sun in the form of light rays is at once absorbed and converted into thermal rays, and these latter cannot pass beyond the air. Certainly there remains to be proven that there is a vacuum beyond the air But from the fact that meteors are not heated until striking the air, we are of the opinion that beyond the air there is an absolute vacuum. This theory leads us to the contrary of the old theory The earth is getting warmer and warmer I am unable to see the flaw in this reasoning, if there is, I should be glad to know it. A We regret that we do not find ourselves able to agree with your argument regarding the heating of the earth. The statement that heat rays will not pass through a vacuum contradicts common experience. The bulb of an incandescent lamp contains a high vacuum. It cools off after the current ceases to flow, and in a very short time is at the temperature of the surrounding air. The heat of the sun comes through space. It is a vacuum. Again, heat and light are the same energy, and not as you seem to think, totally different things. The rays which enter the eye become light If they struck the hand they would be heat. Light and heat are both electromagnetic effects. The earth is continually radiating heat into external space. This is also a matter of common experience. The earth cools every night, and every winter still more so that ice forms over the water and in the ground. This could not be unless the earth loses the heat which in the daytime and the Summer has been given to it by the sun. Finally, the facts are against the hypothesis that the earth is growing warmer year by year. Vegetation has not changed in historical times. Italy has the same grape and olive harvests as in the days of Horace. For over two thousand years the climate of Europe has not altered sensibly. If the earth were growing warmer, this period is surely long enough to show a change of the line of growth of delicate crops, which would now grow farther north than they did in the classical period. Scientists hold that the earth radiates into external space all the heat which it receives from the sun, so that the average temperature remains the same year by year, or at least that the change is not perceptible in a relatively short time. It is also believed that the sun itself must ultimately reach a condition in which it will be unable to furnish its present supply of energy to the earth, and that then the loss of heat from the earth will exceed the supply received from the sun Then will come the end of life on the earth unless the order of things changes

(12940) L. G. B. asks: 1. It appears that the capacity for heat of the metals is low, that of water is high, that of hydrogen is still higher. What is the capacity for heat of a vacuum? A. The capacity of a vacuum for heat is infinite, which means that heat cannot be communicated to a space which is absolutely empty of ordinary matter. The radiation from the sun passes through space to the earth and the other planets without warming the space through which it passes. It will warm any matter which it may strike. 2. When gas is permitted to expand into a vacuum, there is an evolution of heat from the vessel, is there not? Doesn't that show that the vacuum contained heat which the gas drove out? A. So long as gas is expanding there cannot be any heating action from the gas. When a gas is driving other gas before it and compressing that gas, it is doing work upon something, and heat will be produced in the doing of that work. There would be no evolution of heat from the containing vessel at any time, if we correctly understand the use of that word in your inquiry. We mean that there would be no heat given off from the vessel itself which had not been communicated to it from some other source. If any heat was given off by the vessel which did not come from the compressing of the gas, that heat would leave the vessel colder, and must be accounted for in some other way; as, for instance, coming from the vessel because it was hotter than its surroundings, since heat cannot pass of itself from a colder to a hotter place.

NEW BOOKS, ETC.

Standard Organ Building. By William Horatio Clarke. Boston: Richard G. Badger, 1913. 8vo.; 219 pp. Price, $2 net.

"Standard Organ Building" is presented as a text-book to guide church officers and organists in selecting an organ. The average organist may also use it as a reference book to familiarize himself with the mechanical side of his instrument. The mechanical and musical features embodied in good organ building practice are plainly indicated, and the point of view is always distinctly and exclusively practical and modern—only the present development of the organ is dealt with. The author is a well-known organist and a writer of music and musical literature. It is not so generally known that he was for some time proprietor of a large pipe organ factory. Here he determined the complex essentials of the best modern organs, and it is this knowledge—or such part of it as church authorities may find useful—that he imparts through this well-printed and well-arranged volume.

Food and Flavor. A Gastronomic Guide to Health and Good Living. By Henry T. Finck. New York: The Century Company, 1913. 8vo.; 594 pp.; illustrated. Price, $2 net.

Mr. Finck is an epicure. He would have his cook put through years of apprenticeship, as the French do. His gastronomic guide must be judged from the epicurean point of view. To the low-diet enthusiast it is anathema. Its descriptions of native and foreign dishes would ruin the resolves of a St. Anthony But the work has an aim more worthy than that of making the mouth water. It preaches the gospel that flavor is the soul of food, a fact shamefully ignored The psychic factor of desire must precede ingestion, or results will be unpropitious. To each cent spent for nutriment we add five more for flavor Flavor, in short, has an appetizing value, a health value, a commercial value. The evolution of a discriminating appetite and the education of the cook must go hand in hand But your glutton is never an epicure. Rational mastication must accompany the highest enjoyment of food, and in this enjoyment lies perfect assimilation and health It is flavor that stimulates the flow of the digestive juices; it is the digestive juices that prepare the food for the extraction of nutriment. America's hit-or-miss methods of selection and preparation are sharply arraigned, and the blame is to some degree apportioned. Sensual indulgence is held to be a duty. But the mouth must do its share, or the digestive tract has to do it at ten times the expenditure of vital force, and dyspepsia results Taste is limited to the qualities of sweet, sour, salt and bitter. The infinite variations of palatable sensation are to be credited to the sense of smell in combination with these elementary flavors. "Our Denatured Foods" are catalogued and scored in no uncertain language. In "The Science of Savory Cooking," right and wrong ways of preparing food for the table are distinctly set forth Cooking is a science that electricity is soon to make exact. The specialties of France, of England, of Italy, and of Germany are given separate chapters that make us hunger as we read. In "Gastronomic America" we retrace the good old, well-nigh abandoned ways that made our tables tempting in the extreme. The masterly monograph concludes with reflections on the commercial value of flavor and the gastronomic value of odors In many instances, our purveyors are overreaching themselves and are actually inviting loss instead of profit. In butter-making, for example, the greedy manufacturer adds excessive salt because it is cheaper than butter. Yet the more highly salted the butter, the less its market value; in this case dishonest ends defeat themselves! Mr. Finck has years of food-research behind him, and a thorough knowledge of his subject Hence his book is not only delightful reading, but is helpful and instructive to the last degree

Calcul du Beton Arme. Formulés, Tableaux et Abaques. Établis en application des formules de la Circulaire du Ministre des Travaux publics du' 20 octobre 1906. Par Ch. Aubry, ingénieur des Ponts et Chaussees. Paris: H. Dunod et E. Pinat, 1913. 20 francs.

Arduous and thorough labor has gone to the compilation of these formulas, tables, and diagrams, and this labor will save the time and money of the estimator in no small degree. By reference to this work, the worker in reinforced concrete is enabled to arrive at speedy results which would otherwise mean hours of laborious study and calculation. The author admits that into so large a mass of figures some errors may have crept. He will appreciate the report of any such that are discovered. The *abaques* are supplied upon loose leaves in a separate folio. Their convenient form and the clearness lent by their magnitude will not fail to appeal to the reader.

A History of Land Mammals in the Western Hemisphere. By William B. Scott, Ph.D., LL.D., Blair Professor of Geology and Palæontology in Princeton University. New York: The Macmillan Company, 1913. 8vo.; 693 pp.; illustrated with 32 plates and more than 100 drawings by Bruce Horsfall. Price, $5 net.

The author's university colleagues have given him the benefit of their advice and assistance in the preparation of his work, which aims at making a somewhat difficult subject intelligible to the layman. Prof. Scott's own career was determined by a student's fossil-hunting expedition undertaken in the picnic spirit, as it were. The enthusiasm then generated breathes in every line of his work. He has taken great pains to make plain to the reader the methods of investigation, and the part which the successive modifications of bone and teeth play in the reading of these relics dug from the maw of the earth. The introductory chapters are followed by classification and geographical distribution of mammalia and the successive faunas of North and South America; and the body of the history is followed by a discussion of the modes of mammalian evolution. A glossary and index are included, and the illustrations, showing restorations of prehistoric animals and scenes, deserve a word of praise for their care in preparation and for their convincing quality. In type, paper, and cover design the volume is a most attractive example of the publishers' art.

A Cornish Giant. By Edith K. Harper. New York: Spon & Chamberlain, 1913. 61 pp.; 12 illustrations. Price, 40 cents.

"A Cornish Giant" is a biography in pamphlet form of Richard Trevithick, the father of the locomotive. The brief biography is particularly addressed to the people of his own county, but this will not spoil it for those who delight in reading of pioneer inventors and their inventions. The relations between Trevithick and James Watt are amusingly sketched, and as we read we warm toward the solid personality of the six-foot-two blue-eyed Trevithick, misunderstood, jeered, ill-treated, yet always unconquerable—"the greatest and worst-used man in the county."

Ships and Ways of Other Days. By E. Keble Chatterton. Philadelphia: J. B. Lippincott Company, 1913. 8vo.; 308 pp.; 130 illustrations. Price, $4 net.

Uniform with the author's "Sailing Ships and Their Story," this beautiful volume chronologically considers the ways and means by which men built, launched, equipped, and set out with the craft of their various centuries. We learn how men handled these craft, both in peaceful navigation and in war. Still further is attempted; for we are introduced to so intimate a knowledge of the life afloat that we become one with it. None who delight in the landless ocean, and the tumbling and tossing upon it, can fail to have, in reading this story, a sense of dreams come true. He may work the tides with Cæsar and William the Conqueror in their invasions. He may thrust Time back yet farther. For, thanks to old MSS. and curious drawings, we may enter largely into the hulls of the second century, and listen to the exclamations of those who marvel at the dimensions of some newly-completed monster of that day, just as we talk to-day about an "Imperator." Magdalene College, Cambridge, has permitted the reproduction in this work of illustrations from MSS. in the Pepysian Library. One shows a sixteenth century ship designer at work, another, the interior of a seventeenth century ship; still another, the "orthographick simmetrye" of the same. These are but a few of the valuable illustrations to be found in the work.

The Romance of Submarine Engineering. By T. W. Corbin. Philadelphia: J. B. Lippincott Company, 1913. 8vo.; 316 pp.; illustrated. Price, $1.50 net.

Although the submarine boat has been employed as an engine of war since 1776, it is a curious reflection that as yet not one enemy has fallen before it. The only victims have been the crews. Mr. Corbin's book is a popular account and description, not only of submarines, but ship-salving, recovering sunken treasure, the building of breakwaters, and in fact all human accomplishments where it is necessary to work beneath the water. These are themes that invite adventurous handling, and the author has taken full advantage of his opportunity. We read of the feats of the divers, of the breakwaters built with "fifty-ton bricks," and of the secret air-purifying compositions used in connection with diving apparatus. Thus, with thumb-nail sketches of the heroic men and illustrated details of their tools and their work, the author constructs for general reading a very pleasing volume.

Handbuch fur Heer und Flotte. Enzyklopädie der Kriegswissenschaften und verwandter Gebiete herausgegeben von Georg von Alten, Generalleutnant z. D., fortgeführt von Hans von Albert, Hauptmann a. D., unter Mitwirkung von mehr als 300 der bedeutendsten Fachautoritäten. Berlin: Deutsches Verlagshaus Bong & Co., 1913.

One of the most important articles which has thus far appeared in the "Handbuch fuer Heer und Flotte," of which installments 61 to 64 lie before us, is that of General Count von Schlieffen on the Battle of Jena, and the reason why the Prussians suffered defeat in that memorable engagement. The present installments of the Handbuch take the student from "Istein" to "Kaiser-Friedrich-Klasse." The more important articles of a military character are those on the military powers "Italy" and "Japan." No less than eight authorities collaborated in producing the article on "Italy." The article on "India," too, deserves comment. It was prepared by the well-known authority Lieutenant Colonel de Juge. Lieutenant General von Zwehl writes an illuminating essay on Infantry and juvenile military education. Tables, charts, illustrations and diagrams have been freely used throughout these installments.

The Cadillac Company has no intention of marketing a six cylinder car

THE Cadillac Motor Car Company has always believed that there are so many good features in the Cadillac Car, that its advertising space could be best utilized exclusively in acquainting the public with those advantages.

We regret, however, that the occasion arises which makes it appear desirable for us to depart, temporarily, from that policy.

Inasmuch as it is not possible for us to control the "mouth to mouth" advertising with which we are favored, and inasmuch as that gratuitous publicity may sometimes contain elements of inaccuracy, unintentionally perhaps, on the part of the authors, we feel that we would not perform the duty which we owe to the public and the duty which we owe to ourselves, if we did not correct any misunderstandings or misconceptions which may exist concerning the methods, policies and plans of this company.

The pre-eminent position of the Cadillac Car as the "Standard of the World," its recognition as the criterion of excellence in practical construction, are not matters of mere chance.

For eleven years the Cadillac has been manufactured and marketed upon well defined principles. Adherence to those principles has been the dominant factor in Cadillac success.

The Cadillac has never aspired to ideals set by others; it makes its own ideals and raises them higher and higher.

The Cadillac has never striven after the achievements of other plants; it is a school and a model unto itself.

The Cadillac has never been obliged to make apologies for its product. It has never been obliged to smother its past, nor to discredit it by wiping the slate clean and beginning all over again.

The immaterial and the impractical, the fad and the fallacy, the delusion and the shallow "talking point" have no chapter in the "Story of the Cadillac."

The "Story of the Cadillac" is the story of that mechanical and commercial advancement which makes for permanency. The Cadillac product has been only that which its makers knew to be right; that which its makers knew would satisfy and give to the purchaser "value received" in abundant measure.

The policy of the Cadillac Company has ever been to avoid exaggeration and overdrawn statements. Its policy has ever been to under-claim rather than to over-claim.

The Cadillac Company is gratified that the public feels secure in accepting Cadillac representations at their full worth. These representations are so accepted because the Cadillac Company has never misled and because the public could always expect and has always received more than was offered.

The Cadillac Car of today has behind it the experience gleaned in the successful production of the seventy-five thousand Cadillacs which have preceded it—by far the greatest number of high grade motor cars produced by any one manufacturer in the world.

The Cadillac Company is ever alert—its ear is ever to the ground; it feels the throb of the public pulse. Yet never has it yielded to clamor by giving endorsement to principles which would take advantage of the uninitiated or the uninformed, even though temporary benefits might accrue.

The experimental division of the Cadillac Company is not excelled in the motor car industry. We do not believe it is even equalled.

Every design, every appliance, every idea, every principle offered which has a semblance of merit, is subjected to the most gruelling tests

For every idea or feature adopted or considered worthy of the Cadillac seal of approval, scores are discarded.

One reason why most of the new ideas of inventors and manufacturers are first offered to the Cadillac Company is because these inventors and manufacturers realize that with the Cadillac seal of approval, their future is practically certain.

As an example, take the electrical system of automatic cranking, lighting and ignition, first introduced by the Cadillac Company and now used almost universally.

Take also the two-speed axle introduced into the present Cadillac, and which engineering authorities on both sides of the Atlantic are predicting will soon come into general use

Witness this from "The Automobile Engineer" published in London, England. In commenting upon Cadillac engineering progress and Cadillac initiative, it says:—

> "Already there is a very decided movement among other makers to try and provide some type of two-speed rear axle similar to the Cadillac, for 1914 or 1915."

In our experimental division we have built automobile engines of almost every conceivable type and size and have tested scores which we did not make ourselves.

We have built them with one, with two, with three, with four and with six cylinders We have never tried five.

We have cast them en bloc, we have cast them in pairs and we have cast them singly. We have made them with water jackets cast integral and with copper water jackets. We found the latter method most expensive, but the most efficient—hence we use it.

We built cars with one cylinder engines, more than 15,000 of them, and they were good ones "One-lungers" they were called, and they are practically all going yet, after eight to eleven years of service, hundreds of them having passed the 100,000 mile mark.

We built a few cars with two cylinder engines and they were as good as that type could possibly be made. But we never marketed any of them although the rumor was current that we intended doing so.

Yes, and we built cars with three cylinder engines, as good of that type as could be made. Probably few readers ever heard of such a car. Some people thought they wanted that kind and they bought them But not from us. Rumor had it, however, that we intended to market them.

Cars with four cylinder engines! We have built and distributed more than sixty thousand (60,000) of them. That was something more substantial than a rumor.

Cars with six cylinder engines! We have built a number of them in the last four years We have tested them to the utmost, and they proved to be good ones—by comparison. In fact, by comparing them point for point with a number of the most highly regarded "sixes," which we bought for the purpose of making comparisons for our own enlightenment, we failed to find a single car which, in our opinion, outpointed our own, and our own outpointed most of them

These experiments may have given rise to the rumor that the Cadillac Company contemplates marketing a six cylinder car But,—as in the cases of the two and three cylinder cars —such rumor is entirely without foundation. This Company has no such intention.

And we made other comparisons as well, in fact nothing worth while was overlooked or omitted.

Our tests, investigations, experiments and comparisons demonstrated conclusively to us, that a four cylinder engine, designed with the skill and executed with the precision which characterizes the Cadillac engine—and scientifically balanced, affords the highest degree of all 'round efficiency possible to obtain.

These tests further demonstrated that with such an engine, in conjunction with a properly designed two-speed axle, there is obtained an extraordinary range of operating flexibility, an extraordinary reduction of friction, an extraordinary degree of operation and maintenance economy, an extraordinary degree of luxurious riding qualities, and a reduction of vibration, particularly at high speeds, almost to the vanishing point

We have cited the foregoing facts because we believe that the public is entitled to know them, because we believe that we owe it to the public to make the facts known and because we want the public to know that the Cadillac Company leaves no stone unturned, that it spares no expense in its efforts to discover and to provide that which it knows to be right, that which it knows will satisfy and that which will give to the buyer "value received" in abundant measure.

And above all, the Cadillac Company has no intention of departing from that policy.

There can be no better evidence of the appreciation of the Cadillac policy than the fact that there have already been manufactured and distributed, more than 9000 of the 1914 Model Cadillacs, amounting in selling value to more than eighteen millions ($18,000,000) of dollars—a volume of cars which nearly equals, if it does not exceed, that of all other 1914 high grade American cars combined, selling at or more than the Cadillac price, regardless of their numbers of cylinders.

CADILLAC MOTOR CAR CO.
DETROIT, MICHIGAN

The Magic Flight of Thought

AGES ago, Thor, the champion of the Scandinavian gods, invaded Jotunheim, the land of the giants, and was challenged to feats of skill by Loki, the king.

Thor matched Thialfi, the swiftest of mortals, against Hugi in a footrace. Thrice they swept over the course, but each time Thialfi was hopelessly defeated by Loki's runner.

Loki confessed to Thor afterwards that he had deceived the god by enchantments, saying, "Hugi was my thought, and what speed can ever equal his?"

But the flight of thought is no longer a magic power of mythical beings, for the Bell Telephone has made it a common daily experience.

Over the telephone, the spoken thought is transmitted instantly, directly where we send it, outdistancing every other means for the carrying of messages.

In the Bell System, the telephone lines reach throughout the country, and the thoughts of the people are carried with lightning speed in all directions, one mile, a hundred, or two thousand miles away.

And because the Bell System so adequately serves the practical needs of the people, the magic of thought's swift flight occurs 25,000,000 times every twenty-four hours.

Wireless Telegraphy and Telephony

Simply Explained

By ALFRED P. MORGAN

170 Pages, 156 Illustrations Price $1.00 Postpaid

The simplest, latest and most comprehensive popular work published on wireless, for the wireless operator, amateur or professional

THIS is undoubtedly one of the most comprehensive treatises on the subject, and a close study of its pages will enable one to master all the details of the wireless transmission of messages The author has filled a long-felt want and has succeeded in furnishing a lucid, comprehensible explanation in simple language of the theory and practice of wireless telegraphy and telephony.

The book treats the subject from an entirely new standpoint. It is well illustrated by over one hundred and fifty interesting photographs and drawings All diagrams have been made in perspective, showing the instruments as they actually appear in practice. The drawings are carefully keyed and labeled. Many of the photographs are accompanied by phantom drawings which reveal the name and purpose of each part.

A book the wireless experimenter cannot afford to be without. It enables one to design and construct apparatus. Also valuable to the layman

An Organ on Which Color Compositions are Played

(*Concluded from page 162.*)

high degree of pleasure to the sensitive observer. Scriabine, the Russian musician, in a recent orchestral composition, has attacked the corresponding color score, although the work in its twofold aspect has not yet been performed.

For years the term "tone-pictures" has been applied to musical compositions, and the art of orchestral coloring has been made the subject of many treatises. But the new art is not limited by the correspondence of shades of color to musical tones. Immensely more delicate gradations may be obtained in color than are possible in musical sounds. We know, for instance, that in music a dominant note, its major third and perfect fifth together, make up the major chord of that key. Lower the middle note of the chord by a semitone, making it a minor third, and we have the minor chord of that key—a very different thing indeed. Much more delicate gradations would be obtained on the color organ.

The craving of the mind for a definite key seems to hold good of a color composition and, as before remarked, the influence of rhythm is very perceptible. A color composition having a strong march rhythm is as effective as a musical composition in the same style, and Prof. Rimington tells me that he has actually waltzed to a color composition composed in waltz time.

Apart from their purely artistic value, many of these experiments are extremely interesting from the psychological point of view.

Prof. Exner, of Germany, has made investigations to determine how far similar colors affect the majority of people in the same way, but only with regard to single colors, and upon some points he obtained great unanimity of opinion. But the importation of rhythm into color widens the field of such investigations enormously, and numerous possible experiments will at once occur to the reader. Such experiments will doubtless help us in framing an answer to the extremely difficult question: Why are certain color compositions, and not others, considered beautiful? The whole question of the origin of the feeling for beauty is very complex and any aid to the solution of the problem must be heartily welcomed. Prof. Rimington, in his work on the subject, advances several arguments to show the great importance of a developed color sense to a community from the point of view of its commercial prosperity as well as its æsthetic development. It is to be hoped that many other workers will enter this richly fruitful field of investigation, and to America, with its keen interest in new developments, its strong artistic and psychological schools, and its readiness to endow research, we may confidently look for further elaboration of the new and fascinating art of Color Music.

The Coolidge Roentgen Ray Tube

(*Concluded from page 157.*)

the most important contribution to Roentgenology since the birth of that science, and it has found an important place in various fields.

Through the courtesy of Dr. Lewis Gregory Cole, Professor of Roentgenology at Cornell University Medical College, we were able to examine one of the new tubes which has been used with notable success. Not only is the operator able to adjust it with greater accuracy, but he is assured of stability and exact duplication of results, greater flexibility, a greater output of rays, a longer life of the tube, and the absence of indirect rays developed at various parts of the glass bulb which, of course, affect the sharpness of the impression. The new tubes have a vacuum about 1,000 times as great as the vacuum of the ordinary Roentgen ray tube and make use of a tungsten filament as a cathode, the material out of which, as every one knows, the filament in the ordinary tungsten incandescent lamp is made. This cathode, unlike that in the older type of tube, must be heated in order to render the tube active and capable of being ex-

INQUIRIES

Inquiry No. 9347. Wanted the name and address of an industrial school where shoemaking is taught in all its branches

Inquiry No. 9348. Wanted the name and address of manufacturers having useful household necessities, with a view to obtaining exclusive territory for a house to house canvass

Inquiry No. 9349. Wanted the names and addresses of the makers of machinery for making Malt Tonic, also a machine for making grease, and machines for applying plaster (Cement Gun).

Inquiry No. 9350. Wanted the name and address of the manufacturer of a printing press for the printing of tapes for clothing The machine should preferably be worked by hand.

Inquiry No 9351. Wanted to make some article out of wood which could be made from 2 inch [illegible], by party having 75,000 or more feet of waste per year which is now used for fuel.

Inquiry No. 9352 Wanted the name and address of a person who is in a position to get the state or county agency for articles of merit that can be sold to business houses or others at $2.00 or over. No kitchen utensils desired

Inquiry No 9353 Wanted the name and address of a manufacturer who can make flexible oil cans.

Inquiry No 9354. Wanted the name and address of a manufacturer of a machine which will stitch silk around small metal rings.

Inquiry No. 9355 Wanted the name and address of the maker of triplex glass.

Inquiry No. 9356 Wanted the name and address of a manufacturer who can build an *automobile wheel*, also a *cigar vending machine*. Concerns in the middle West preferred.

Inquiry No. 9357. Wanted the name and address of a manufacturer of a machine for scalloped paper favors and cups.

Inquiry No. 9358.—Wanted the name and address of maker of a machine to cut all granulate leather.

Inquiry No. 9359 Wanted the name and address of a firm that makes razor blades for all makes of safety razors

Inquiry No. 9360. Wanted the name and address of parties making pipe fittings such as ferrules, shanks and bowls such as could be used in the making up of calabash pipes for smoking.

Do You Want to Sell Your Invention?

Every patent commercially valuable would be quickly bought at a good price, or money promptly furnished for its exploitation, if investors could be (1) absolutely assured of its validity, and (2) insured against the danger of infringement.

Make your patent salable by insuring it!

We issue a policy which will insure its validity and protect it against infringements. We furnish expert reports on the commercial possibilities of patents and novelties We arrange, through our world-wide connections, for their purchase outright or for funds with which to put them on the market.

If you wish to sell your invention, or to [illegible] royalty basis, write for particulars to the [illegible]

J. M. WILSON, Patent Attorney
37 Liberty Street NEW YORK CITY
Representing The Letters Patent [illegible]
[illegible]

[illegible] When a current from a storage battery raises the tungsten filament to the required temperature the electrons are liberated from the cathode by the high potential current ordinarily employed and furnished from an induction coil or transformer.

The penetration of the rays from the tube depends upon the rapidity with which the electrons are thus shot out from the cathode, and this speed is controlled by regulating a low potential current from a storage battery in circuit with the tube, which acts to generate heat in the cathode filament. With one of the new tubes using a filament of twenty-five milliamperes, the stability of the tube will remain permanent for fifty minutes without perceptibly changing the penetration. This gives a Roentgenogram with a uniformity of excellence which has never before been obtained; and after the tube is adjusted to the desired degree of penetration for any given part of the body it may be excited with any desired milliamperage from 1 to 200, for the time required for a correct exposure. Uniform results can be obtained by decreasing the current and increasing the exposure or *vice versa*.

The controlling apparatus is such that an exact duplication can be obtained and, at the same time, the tube is so flexible that it can be operated at a penetration so slight as to show the fine blood vessels of the hand or foot at one instant, while at the next it can be increased so that a penetration far exceeding anything possible with the ordinary tube can be secured, thus making it available for all kinds of Roentgenographic and therapeutic work.

The life of the new tubes is placed by Dr. Coolidge at a minimum of a thousand hours of constant running, so that the tube is more likely to be impaired as the result of accident than from wearing out. The new tube avoids the detrimental effect of the indirect rays generated in the wall of the anterior hemisphere of the tube by secondary or deflected cathode streams which blur the image and give rise to secondary rays in the tissues of the body interposed. To one seeing the apparatus for the first time the utter absence of fluorescence in the glass is most marked.

With the new tube a scale of length of exposure and current required with different lengths of spark gap has been compiled which shows exactly what is needed in photographing the various parts of the body. In one instance ten exposures were made in 4/10 of a second of actual time With the stomach, using a spark gap of five inches and a current of 110 milliamperes, the time of 0.06 second was required, while for the detail of the spine, using a current of 30 milliamperes, 15 seconds would be required.

The original tests made in the research laboratory with experimental apparatus on animal tissue and strips of metal were repeated in Dr. Cole's laboratory and a series of test plates were made which showed clearly the differences obtained by varying the conditions in a number of exposures on the same subject.

A New Scheme for Selling Patents

IN a neighboring city not far from New York, there is a patent bureau bearing a foreign name, which puts forward a claim of having special facilities for selling patents abroad. The carefully worded correspondence which this bureau carries on with the inventor is alluring in character and is designed to entice the unsuspecting client into its fold.

As soon as a patent is issued in the United States, an attractively worded letter is received by the inventor, informing him that the parties of the first part make frequent trips to Europe and are in direct contact with European manufacturers and act as their agents, and that such manufacturers are anxious and eager to undertake the manufacture of this particular patent on royalty basis, or buy the patent outright for a reasonable amount. They usually state that they consider the patent very valuable for the European market, and "we could contract the manufacturing right on a strictly commission basis of ten per cent." They then state further:

"If you have no foreign patents, would you consider an offer for the manufacturing rights? Are you open for an offer? Kindly reply. We mean business."

All of the above suggestions are in the body of the letter and are typewritten. Then written in ink in a broad and scrawling hand, is the following: "We are able to close a contract with a German manufacturer."

We are constantly receiving letters from inventors who have received these circular letters from the parties above named, and who are considerably excited over the prospect of closing a contract for the sale of a foreign patent when perhaps no patent has yet been obtained there. It may or may not occur to the inventor that it is a singular thing that within a few days of the issuing of his United States patent a German manufacturer should be eager to step in and make a contract for the German rights. In his eagerness, however, to launch the new enterprise the inventor is usually taken unawares and does not reason out the inconsistency of the proposition.

One of our correspondents wrote to the "Patent Bureau" as follows:

"*In your former* letter of December 13th you say in a postscript, 'We are able to close a contract with a German manufacturer.' I suppose by this that you mean you have a definite manufacturer in view with whom you know that you can make a contract. I asked you specifically on this in my letter of December 23rd, but you disregarded my inquiry in your last letter.

"When you write please give me the fullest information on the matters I have requested, as a fair and clear understanding is very essential for doing business satisfactorily."

In reply to this letter, which the Editor has before him, this question in regard to who the manufacturer is who is ready to sign the contract, and whether there is such a definite manufacturer ready to sign the contract, remains unanswered. We suggest to the guileless inventor who may be enticed to open correspondence with these parties to assure himself in regard to these facts before entering into any contract with the parties in question We are of the impression that the inventor will discover before any negotiations can be entered into that a considerable payment will be exacted in each country before any disclosure will be made.

They state in a letter which we have before us:

"Your article must be offered for sale in a businesslike manner to present literature in their languages, with cuts, photos, etc. Can you submit us such literature, cuts, samples, etc.? Without the same we cannot do anything. To undertake the sale, to have such literature made in each country, in their respective languages, we charge you $.... for each country, and we will send you proofs of the same."

If the reader has a patent which he wishes to sell in a foreign country we suggest before making any arrangements involving the payment of any retaining *fee that he shall demand full information* in regard to what success others have achieved, and who the parties are who are so anxious and eager to close a contract in some foreign country almost simultaneously with the issuance of the patent here.

A Recent By-product Utilization in American Soap Manufacture

By L. Lodian

IN all soap manufactories there accumulates in due course a soap-kettle refuse known in the trade terminology as the "nigre." What to do with this "nigre" has long been a problem to the student of the soap industry. True, he could work some of it up with low-grade colored soaps, make it into the so-styled black tar soaps or use it for a brown-black dog soap as a flea killer. But tar soaps are of exceedingly limited use, while any soap white or colored is a good destroyer of fleas, as the alkali lather attacks them instantly.

In Europe, for over a century the

"nigre" has been used for the turning out of the course brown bar-soap known as carbolic soap (10 to 20 per cent of the acid being worked into the "crutch" or kettle-boil), and this is extensively used there as a disinfecting hospital-floor or prison-floor scrubbing soap; while it also makes a capital cleansing soap for carpets and garments. On the other hand, in America carbolic bar-soap is scarcely known, especially in the city retail stores, while its use as a fair-grade toilet soap is almost a negligible factor. The odor is disliked by the vast majority of people, so there has never been any chance for the "nigre" in that direction.

So what to do with the "nigre" remained a question. It was thought to be worth more than for fuel use, or for running away as waste, so one large company decided to experiment; and two years ago it put on the market a quantity of cases of the kettle-refuse soap, at a price lower than any other soap, i. e., two big laundry size cakes for five cents. Its salesmen said that it would never succeed, that its blackish-brown color would be against it.

To the surprise of the Jersey City nigre-soap outputters calls came from retailers for more cases, and the manufacturers constantly replied that there was not enough "nigre" to supply the demand. This condition has continued up to the present time

What is all the more remarkable is that the American firm has succeeded in marketing a far more difficult refuse-product than ever appeared in Europe. What is wasted there is here utilized. The veriest dregs of the soap-kettle, consisting of refuse membraneous-tissue particles and even the tiny sand-like bony, gritty minute portions which settle to the bottom of every kettle, are all utilized now in this nigre-soap An advantage too lies in the fact that in washing practice, these fragments cause a slight friction sufficient to form a foaming lather

Nigre-soap must necessarily be a cheap compound, a resin-and-salt product; consequently it sweats in humid weather like the low-priced toilet-soaps to an almost unpleasant stickiness, and "blooms" or effloresces some of its elements in dry spells In the wash though it acts and wears well and can be used on the most delicate bleached silks, which properly rinsed show a snow white appearance, as the foam from the soap has little color—a feeble dinginess only The cake wears down without breakage to an almost paper-thin tablet

Altogether, considered as a by-product, this nigre-soap is a creditable one, and it reveals what may be accomplished by trying and what one firm has successfully marketed in the East, others in various sections of the country might duplicate.

The refuse membraneous-tissue dregs or filaments, in an extremely comminuted form, naturally segregate in the molten grease, and after working into soap, they are often still found in the cake in an agglomerated condition—dissolving, however, in the wash uniformly with the rest of the soap The congregated refuse tissue seen here and there in parts of the contrasting smooth-grain black-brown soap, often presents an almost picturesque appearance, especially when wet, as of rare-marked mahogany specimens, or beautiful dark-hued fossils

According to Lamborn, the ensuing analysis of the average nigre soap-kettle refuse explains its make-up.

Water	64.32 per cent
Soap, anhydrous	29.04 per cent
Alkali, free, NaOH	0.52 per cent
Alkali, combined, Na_2CO_3	2.17 per cent
Non-determined	3.95 per cent

A soap works instances a fraudulent use of the by-product in low-grade or certain dark-colored toilet soaps, it also lists all of the dishonest "fillers"—talc, barytes, earths, mineral fillings, and the other tricks for weighting soaps; and these are mentioned so that the reader may be warned against their use.

The American Forestry Association has just elected Henry S. Drinker, president of Lehigh University, and P. S. Ridsdale, as its president and secretary, respectively.

Cushions Tires Springs

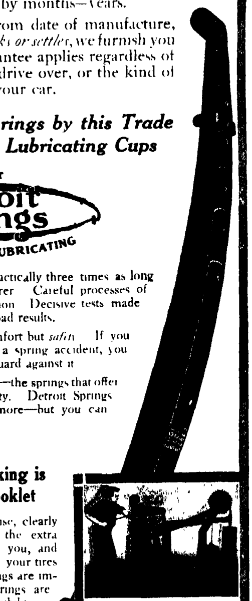
of the Three, SPRINGS are the Most Important Element of Comfort

WHEN you think of comfort, think of springs — Detroit Springs. Get good cushions and tires, of course. But, above all, *demand the right springs* — the flexible springs. For without them the best cushions and tires are powerless to protect you from road shock.

Detroit Springs absorb the pound and vibration of the road. They take the burden off the tires Ask *less* of your tires and they'll work *longer* for you.

Detroit Springs cushion the mechanism of your car, lengthening its life by months—years.

If within two years from date of manufacture, your Detroit Spring *breaks or settles*, we furnish you a new one. This guarantee applies regardless of what kind of roads you drive over, or the kind of service you exact from your car.



Identify Detroit Springs by this Trade Mark and by the Lubricating Cups

RESILIENT
Detroit Springs
SILENT TRADE MARK SELF-LUBRICATING

We make the guarantee practically three times as long as that of the car manufacturer Careful processes of manufacture are our justification Decisive tests made in our factory assure you of road results.

We guarantee not only comfort but *safety* If you have ever seen the results of a spring accident, you know how necessary it is to guard against it

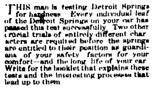
Demand Detroit Springs—the springs that offer you a definite service and safety. Detroit Springs cost the car maker a little more—but you can have them if you insist

Another valuable feature—

Freedom from Squeaking is Explained in Our Booklet

It's worth reading Concise, clearly stated, interesting *reasons* for the extra comfort Detroit Springs give you, and the *causes* of the longer life of your tires and car You learn why springs are important and how Detroit Springs are prepared for their responsibilities. The booklet is mailed free Address

Detroit Steel Products Company
2256 East Grand Blvd.
Detroit Michigan



THIS man is testing Detroit Springs for hardness Every individual leaf of the Detroit Springs on your car has passed this test successfully Two other crucial trials of entirely different characters are required before the springs are entitled to their position as guardians of your safety factors for your comfort—and the long life of your car Write for the booklet that explains these tests and the interesting processes that lead up to them

Soldering and Brazing

for nearly all metals, including such difficult ones as cast iron and aluminium, have been the subjects of hundreds of paragraphs in the Scientific American Supplement. We quote a few of the more important articles, as follows:

Scientific American Supplement No. 1673—*Full Instructions for Mending or Welding Cast Iron*, gives both brazing solders and fluxes necessary

Scientific American Supplement No. 1713—*Brazing Cast Iron and Other Metals*, gives detailed instructions for the whole operation, and formulas.

Scientific American Supplement No. 1644—*Soldering and Soldering Processes*, gives broad general information, and contains in particular a method for pulverizing solders and alloys of great use

Scientific American Supplement No 1667—*Some Soldering Appliances*, describes the blowpipe and the furnace in their various forms.

Scientific American Supplement No. 1481—*Soldering of Metals and Preparation of Solders* gives many formulas for soft and hard solders and fluxes

Scientific American Supplement Nos. 1610, 1622, 1628 contain a series of three articles on Solders, covering the entire range of solders for all metals No 1628 contains formulas and instructions for *soldering aluminium*

FOR 80 cents—the price of the eight numbers, postpaid, the purchaser of these Supplements has a complete treatise on the subject of Soldering and Brazing, containing formulas of the greatest value.

EACH number of the Scientific American or the Supplement costs 10 cents. A set of papers containing all the articles here mentioned will be mailed for 80 cents. Send for a copy of the 1910 Supplement Catalogue, free to any address. Order from your newsdealer or the publishers

MUNN & CO., Inc., 361 Broadway, New York City

The Gyroscope

The mysterious behavior of the gyroscope is a source of wonder to everyone. From a curious toy, the gyroscope is being developed into a device of great practical value Its theory and its method of action are set forth up to the latest moment in the Scientific American Supplement. The following numbers are of great interest and usefulness·

Scientific American Supplement No 1501—Treats of the Mechanics of the Gyroscope A clear explanation without mathematics

Scientific American Supplement No 1534—"Little-known Properties of the Gyroscope describes a peculiar action not generally observed, and discusses the effect of this property upon the motions of the planets

Scientific American Supplement No. 1864—The Gyro Compass, its principle and construction

Scientific American Supplement No 1621—The Gyrostat for Ships describes the construction and application of the principle to prevent rolling of vessels

Scientific American Supplement No. 1943 Gyroscopic Stabilizer for Ships, by Elmer A Sperry.

Scientific American Supplement No 1694—Gyroscopic Apparatus *for Preventing Ships from Rolling, takes up the Schlick invention* described first in No 1621, and discusses its action and results fully.

Scientific American Supplement No. 1645—The Theory of the Gyroscope is an excellent article, treating the subject mathematically, rather than popularly

Scientific American Supplement No. 1649—The Gyroscope, is an article giving a full discussion of the instrument without mathematics, and in language within the comprehension of all interested.

Scientific American Supplement No. 1716—A Recent Development *in Gyroscopic Design, illustrates a new form of gyroscope* and mounting adapted to engineering uses

Scientific American Supplement No. 1643—The Gyroscope for Balancing Aeroplanes, takes up this interesting field, which the gyroscope alone seems capable of occupying.

Scientific American Supplement No 1741—Gyroscopic Balancing of Aeroplanes, tells of various suggested methods of maintaining equilibrium

Scientific American Supplement No. 1773—The Wonderful *Gyroscope*, gives diagrams of the Gyroscope and its action, and applications to maintaining stability of ships and monorail trains

Scientific American Supplement No. 1872—The Mechanical Principles of Brennan's Mono-rail Car A lucid exposition

Scientific American Supplement No. 1814—The Regnard Aeroplane, describes the latest design of aeroplane stabilizer, from which great things are expected

Scientific American Supplement No. 1861—The gyrostatic force of rotary engines its nature and significance for aviation

EACH number of the Supplement costs 10 cents. A set of papers containing all the articles here mentioned will be mailed for $1 50

SEND for a copy of the 1910 Supplement Catalogue, free to any address. Order from your newsdealer, or the publishers

Method of removing the outer bark in preparation for setting the apron and the cup for a flow.

Streaking or chipping. Starting the face. Note the nail (below the apron) upon which the cup is set.

Showing the method of setting the apron in orchard turpentining after removal of the bark of the tree.*

Prolonging the Naval Stores Industry

By Samuel J. Record, Assistant Professor of Forest Products, Yale University

THE future of the naval stores industry in the United States is a matter of grave concern. Wasteful methods of boxing and chipping are carried on in advance of logging operations and no provision is made for continual production. Long leaf and Cuban pines of the South have long been the chief source of the world's resin supply, but the stands of these trees are rapidly being cut. The demand for naval stores, however, is increasing, and this has led to the boxing of smaller trees and of species which formerly were not considered worth while. With depletion of the forests the industry has advanced farther and farther west until practically the whole range of long leaf pine has been covered. There is no other region to exploit unless it be the far West. Investigations of the yield of resin from western pines indicate a possible future for the naval stores industry, but it can never approach conditions in the south Atlantic States.

Decrease in supply has also stimulated the distillation of pine wood and while there is considerable prejudice against the turpentine thus obtained it nevertheless has a promising future. Improved methods of distillation are coming into use which overcome most of the objections to wood spirit.

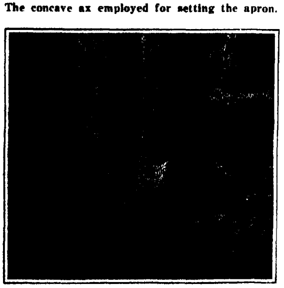
For ten years the United States Forest Service has been experimenting with improved methods of turpentine orcharding. *Instead of the destructive box cut* into the base of the tree, thereby weakening it and rendering it particularly liable to fire damage, a system of cups and gutters was shown to be successful. The adoption of this method has been slow and even at the present time the old way is still common.

The next important feature of turpentining presenting itself for investigation was in regard to the proper depth, width and height of the wound made on a tree in chipping. Some of the results of the comparative experiments conducted on a commercial scale under normal conditions demonstrate that combined shallow and narrow chipping increases the yield; that the number of trees killed is decreased; and that the damage to the lumber in the butt cut of chipped trees is reduced.

Light cupping, that is, restricting the operation to timber over twelve inches in diameter, and closely limiting the number of cups per tree, has proved to be highly advantageous since it prolongs the period during which a crop can be worked and by exempting the young trees prevents the exhaustion of the timber available for turpentine in future, thus assuring stability and perpetuity to the naval stores industry.

Resin will not continue to flow indefinitely from a cut, hence frequent chipping (once a week or oftener) throughout the season is necessary to maintain the flow. Cuban pine bleeds much longer than any others, producing almost no "scrape." The thickness or rather the height of the chip taken off determines the rate of advance of the face up the tree. The more cut off at a time the sooner the face will get beyond the reach of the chipper. It has been demonstrated that a thin shaving will accomplish as good or even better results than a heavy cut. With the ordinary hack, however, this is difficult to regulate, and a new hack has been invented which works on the principle of a safety razor. The thickness of chip can be gaged accurately even after repeated sharpening of the hack blade. It is so made that the inside edge is flat instead of curved, thus leaving the cut face smooth instead of scalloped. This facilitates the flow of resin into the cups.

The operation of making the groove in the tree. The concave ax employed for setting the apron.



A fairly typical face. The hack, which shaves on the principle of a safety razor, lies beside the tree.

The question of running the face spirally instead of straight up the side of the tree is being considered. The advantage of the spiral would be in extending the length of time a tree could be chipped before the face got beyond reach of the long-handled hack. It might at first appear that the effect of a spiral face would be to girdle the tree as soon as it had extended entirely around. Such is not the case, however, since the movement of the sap is not in straight lines, but from one cell to another through pits in the side walls. The sap stream would accordingly follow the spiral of uninjured wood without material interruption.

A method of resin gathering for which a great deal has been claimed consists of boring slanting holes in the sapwood and draining the resin into a closed cup. This was supposed to prevent the closing of the resin ducts by oxidation of the resin, thus permitting a continuous flow. This and similar methods fail to take into account the physiological processes involved in resin formation.

Resin is a waste product resulting from the vital processes of growth. It is not, as many assert, a healing balsam especially produced by the tree to protect wounds, such a function of it being purely incidental. In the change of starch into exactly the kind of food the plant wants a complex substance is left over as a *by-product. This is called resin and is found in* parenchyma cells since they alternately store up and give out starch and other plant food, according to the season.

If several resin cells or parenchyma cells are close together the amount of by-product (resin) becomes too large to be contained in the cells and is excreted into intercellular spaces. Such spaces are known as resin ducts and are characteristic of the wood of our pines, spruces, larches and Douglas fir. Most of them extend up and down the stem, but many occur in the large medullary rays. These ducts are for use in the storage of resin and not for its transfer from one part of a tree to another. In this function as well as the absence of a wall of their own they differ from the vessels of hardwoods. None of our hardwoods contain resin ducts in the wood, though many species of *Dipterocarpaceae* in the Philippines are so characterized. The milk of dandelion, of milkweed, and the latex of rubber trees is also a by-product similar to resin in formation.

In tapping a tree comparatively little resin is actually secured from the ducts already in the wood. The main flow is not out of the old ducts like sap out of cut vessels, but is from new ducts which arise as a consequence of the injury. Wounding, such as chipping, stimulates the vital processes at the seat of injury and greatly increases the by-product, resin, and in consequence there is an increase in the number of ducts necessary to contain it. It is from these secondary ducts that most of the commercial yield of turpentine is secured.

The first wound results in the formation of a number of new or secondary resin ducts from both above and below the injury, the length of those above being greater than those below. Subsequent chipping of course affects only the upper edge of the first wound. The first wound is usually made in winter when all hands are engaged either in placing the cups on the

(Concluded on page 186.)

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The Problem of Our Navy

THE SCIENTIFIC AMERICAN commences in this issue the publication of a consecutive series of articles on "The Problem of Our Navy," than which problem, as affecting our international interests and our standing as a great world power, there is no question before the people of the United States and its Congress of greater and more pressing importance.

During the past thirty years, or since the time when a Democratic Administration commenced the construction of an entirely new navy of steel, and set afloat such cruisers as the "Chicago," "Olympia," and the vessels of "The White Squadron," and that famous trio of battleships, the "Oregon," "Massachusetts," and "Indiana," the SCIENTIFIC AMERICAN has recorded the steady growth of the Navy, *so far as its materiel is concerned*, and by photograph, drawing and descriptive text, has kept the public in close touch with the various ships, as they came from the builders' hands and went into active commission.

We feel that the time has now come to take a broader view of this most important subject, and show how vitally the Navy is related to those stupendous international policies, such as the Monroe Doctrine, the Integrity of China and Asiatic Exclusion, upon which the United States has recently taken such a bold stand—with regard to which it is at this very moment assuming an attitude that admits of no compromise whatsoever.

The spirit of the articles will be at once laudatory and critical, and as an evidence of the happy combination of these two attitudes, we direct special attention to the first of the series, by Assistant Secretary of the Navy Franklin D. Roosevelt, as published elsewhere in the present issue.

Canal Tolls Sophistries

DISPATCHES from Washington indicate that the President will meet with strong opposition in the House of Representatives to his proposed repeal of that clause of the Panama Canal Act which exempts coastwise traffic from the payment of tolls. If Representative Underwood, the Democratic leader of the House, is correctly reported in the New York *Times*, he is making an investigation of the probable effect of an amendment to the Canal Act extending free tolls on their domestic commerce to all nations. How this would better the situation we fail to see. To meet the fixed and operating charges of this $400,000,000 enterprise will require the gathering in of every dollar of legitimate earnings that it can secure. Exemption of our coastwise traffic would cut down the revenues enormously; and Mr Underwood's proposal to exempt the domestic commerce of all nations would not only reduce the revenues in a still larger measure, but would make the discrimination most painfully apparent in the case of those nations that have no domestic commerce to send through the canal.

Mr. Underwood is quoted as saying that in the United States we have never charged domestic commerce a toll for the use of any waterway improved at the expense of the Government, and that to do so at Panama would be an innovation. Well, what of it? All new legislation is more or less of an innovation, and in this case the innovation is necessitated by treaty obligations of the clearest and most binding character.

It seems to us that there is more of sophistry than good logic in arguments such as these, and especially in the following: "Now mark this inconsistency," Mr. Underwood is quoted as saying. "The rules for the government of the Suez Canal, as embodied in the treaty of Constantinople, are those we adopted for the government of the Panama Canal. All the principal powers of Europe signed that treaty. Yet, though Russia, one of the signers, makes an annual appropriation to pay the tolls of her domestic commerce through the Suez Canal, Great Britain never has protested." But why should she? The Hay-Pauncefote treaty leaves all nations free to pay back to the shipping companies amounts equal to the tolls charged for passage through the Panama Canal, if they feel disposed so to do. That is a question affecting the individual governments and the shipping companies which may use the Canal. The treaty between the United States and Great Britain takes no cognizance of such matters. If the United States Government charged equal tolls to our coastwise shipping and then voted from the Treasury sufficient money to repay these tolls to the coastwise shipping companies, there could be no protest from Great Britain or any other maritime country against such procedure

Alphonse Bertillon

IN the popular mind the fame of the late Alphonse Bertillon rests entirely on the introduction of the anthropometrical and finger print methods of identifying criminals. Magnificent as was the achievement of co-ordinating the police headquarters of the world, so that it is now a matter of routine for the bureaus of criminal identification in the larger American and European cities to exchange measurements and fingerprints, Bertillon's reputation rests on a broader basis of scientific achievement. Indeed, the anthropometrical system is eventually bound to give way to Galton's fingerprint method, which Bertillon was reluctantly compelled to accept and introduce.

What the police forces of our great cities owe to Bertillon is the injection of a scientific spirit into the work of tracking criminals. His *Bureau d'Identification judiciaire* has been a model laboratory in which the police of the world have been shown how the evidence of crime may be studied scientifically. Its counterpart should be found in every American city—a wish that will probably not be realized for decades to come. When the full significance of the scientific methods that Bertillon introduced into the French police system is appreciated, we will wonder why we ever tolerated the present system, why criminals in this twentieth century are still tracked by detectives who are nothing but promoted policemen and who can use only in the crudest kind of way, the clues that are placed at their disposal. Some day there will be found at the head of every detective bureau a man with Bertillon's outlook and scientific spirit—a man who will have as his subordinates not uneducated policemen and detectives, but men trained to deal with crime in a systematic scientific way.

Requirements of the Automatic Train Stop

WE recommend for the study of all who are engaged on the automatic train stop problem a review, in booklet form, by Mr. Joseph W. Buell of Washington, of the principles underlying the design and construction of automatic stop apparatus as applied to the control of railroad trains. The author, himself an inventor of a well known system, has devoted many years to the study of cab signals and automatic stops and is well qualified to discuss the various branches of this subject and its relation to wayside signaling.

At the outset it is pointed out that previous developments in railway signaling have had to meet exacting requirements; and that the demand for greater efficiency in safeguarding railroads by the employment of automatic stops, necessitates that their design and operating principles be subjected to the same rigid treatment with respect to their pre-requisites, as has characterized previous development in the existing methods of signaling.

After a brief discussion of the engineering rules that govern the problem, some space is given to the physical side of the question and particularly to the perplexing problem of satisfactorily providing either a mechanical or an electrical means for transmitting an impulse from the track to a traveling locomotive in order to actuate the mechanism thereon, and to doing this in as reliable a manner as has been found in the automatic production of a roadside signal on a mast or post.

The various systems of automatic stops offered for approval may be conveniently classified as six distinct methods or types for communicating motion, or producing an electrical effect, on a traveling locomotive by reason of a danger-giving condition of the track. Mr. Buell points out that, in the study of these systems, every aspect of the problem [illegible] simple and there is provided a method for [illegible] the real value of any one of these systems [illegible] considering their relative merits we must [illegible] attention to the vital consideration of the [illegible] excellence of the means used for establishing [illegible] connections, or contacts, between the track and the locomotive. Furthermore, it must be borne in mind that in whatever manner this be done, it is imperative that the operating principle involved shall satisfy the fundamental requirements of observing the engineering rule of "failure on the side of safety."

In dealing with the problem of establishing connection or contact between the track and a traveling locomotive Mr. Buell has classified the different systems, aside from the one which transmits an electrical or magnetic impulse through the air, as follows:

First, a contact obtained by impact or blow. Second, a yielding contact obtained by pressure of a [illegible] part, carried by the locomotive, upon a stationary part on the track. Third, a rolling-wheel contact, obtained by the pressure of the wheels of the locomotive on the traffic rail. Every step in the development of each type is clearly set out, and a brief account is given, in a practical but scientific way, of the various types of automatic stops such as the Trip, Third-Rail, Ramp, Wireless, etc., and the author sets forth impartially the advantages claimed for each; how their merits should be respectfully judged by accepted standards; and at the same time the disadvantages involved in each type are shown. The author finds a prospect for the survival of the Ramp type and the Rolling-wheel Contact Type. The latter he regards as the ideal one for reasons that are given at some length.

There is a demand for literature of a compact but comprehensive form dealing with this problem; and a reading of this booklet will be found useful to inventors in clearing the air, as it were, and setting them on firm ground with regard to fundamental principles and practical requirements.

The Next 900-foot Atlantic Liners

THAT the 900-foot transatlantic liner is a profitable investment is proved by the fact that this summer there will be three ships in service between Europe and America which will be over 900 feet in length. These will be the "Imperator," which, during the winter months, has been undergoing considerable modifications, the new "Aquitania" of the Cunard Line, which is due here next June, and the "Vaterland," of the Hamburg-American Line, which will make her maiden voyage to New York in the early summer. The "Aquitania" is 901 feet long, the "Imperator," [illegible] feet, and the "Vaterland," 940 feet, these being the lengths over all. In the same class should be mentioned the White Star liners "Olympic," now in service, and the "Britannic," which was recently launched and is being rapidly pushed to completion.

The "Aquitania" will be an enlarged "Mauretania," with a displacement about 50 per cent greater. She will be driven by quadruple turbines working on four shafts, and her horse-power will be about the same as that of the "Mauretania;" although the speed, due to the great increase in displacement and the somewhat fuller lines of the hull, will be less. The "Mauretania" has crossed the Atlantic at an average speed of 26.01 knots, and it is expected that the "Aquitania" will be capable of a sustained sea speed of something over 23 knots. With her full equipment on board, the new ship will have a displacement of about 55,000 tons. With a length on deck of 901 feet, she has 97 feet of beam and a plated depth of 64 feet.

The safety elements in the "Aquitania" are broadly similar to those embodied in the "Lusitania" and "Mauretania." For five hundred feet of her length she consists of a shell within a shell, the coal bunkers being carried at the sides of the ship in the wake of the boiler rooms. The inner wall of the bunkers is about 15 feet from the outer shell, and the whole of the boiler and engine spaces is subdivided by six bulkheads extending from side to side. These bulkheads have been specially stiffened; and with them is associated a watertight deck in the neighborhood of the water line. An interesting fact is that the ship will carry two 40-foot and two 30-foot motor lifeboats, which, in case of emergency, will suffice to tow all the other boats, including twenty-five large rowing boats and a large number of the collapsible type.

The "Vaterland," an enlarged "Imperator," is 940 feet long with 100 feet of beam and a plated depth of 73½ feet. She will differ from the "Imperator" in underwater form, being constructed with a cruiser stern and will carry a balanced rudder operated by steering gear which will be entirely below the water line. She will probably be a knot or more faster than the "Imperator," and of four or five thousand tons greater displacement, this at full load being something over [illegible] tons. A sister ship of equal dimensions and beam is under construction at the Blohm & Voss yards, where the "Vaterland" is now receiving her finishing touches.

Engineering

[illegible] the Elevated Railroad.—The Inter[illegible] Transit Company, of New York city, has [illegible] contract for third-tracking the Second, [illegible] Avenue Elevated Lines. The esti[illegible] the work is about $17,000,000.

[illegible] New Railroad Construction.—Statistics [illegible] show that there has been a decrease in the [illegible] new lines under construction from 2,500 [illegible]y 1st, 1912, to 1,522 miles on January 1st, 1913. [illegible]ing to the *Railway Age Gazette*, the out[illegible] construction is not promising for the year 19[illegible] will probably witness a still further decrease. In [illegible] there are 1,568 miles of new line under con[illegible] compared with 3,500 miles one year ago.

[illegible] Coal in 1913.—According to the official esti[illegible] United States Geological Survey, the output of [illegible] the United States during 1913 amounts to be[illegible]0,000 and 575,000,000 short tons. Edward W[illegible], coal statistician of the Survey, has stated th[illegible] mining industry, in spite of an increase of [illegible] over the year 1912, was perfectly normal, [illegible] figures are to be taken as showing the great industrial activity throughout the country.

Ships that Break in Two.—In our recent editorial entitled "Ships that Break in Two," it was stated that an accident of this character occurred to the British destroyer "Viper." The vessel that broke in two was the sister destroyer "Cobra," which foundered in the North Sea on September 18th, 1901, with a loss of seven lives. The Admiralty inquiry showed that her loss was due to structural weakness. Curiously, the "Viper" was lost in the same year through running aground in the Channel Islands.

A Substitute for "Watch Your Step."—The Interborough Rapid Transit Company has perfected a mechanical gap-filling device which will be used at subway stations which are on a curve. It consists of a grated segment of the platform which is thrust forward, filling the gap between car and edge of platform, the movement being made just before the train comes to a stop. The grating remains in this position until the train has started and moved a distance of 7 or 8 feet. The gap-filler is operated by electro-pneumatic cylinder action.

Revival of the Big Sailing Ship.—The development of the heavy oil engine bids fair to bring about a revival of the big square-rigged sailing ship. The latest of this type is a truly magnificent vessel, "The France," launched by the Chantiers de la Gironde at Bordeaux. She is 430 feet long, 55⅜ feet beam and draws 24 feet when loaded to a displacement of 10,650 tons. Her auxiliaries consist of twin Schneider-Carels oil engines of 925 horse-power, which drive the ship at a speed of 10½ knots, the fuel consumption on the brake test being 0.45 pound per brake horse-power per hour. Her lines are finer than those of the ordinary tramp steamer, and under sail alone she should be capable in a whole-sail breeze of making 16 knots.

Stopping Express Trains in Their Own Length.—A most important development of the air brake was demonstrated in recent experiments on the Pennsylvania Railroad when a twelve-car steel train, nearly 1,000 tons in weight, running 60 miles an hour, was stopped within its own length of about 1,000 feet. The new Westinghouse brake may be operated with pneumatic or electric control, and it embodies among other improvements two shoes for each wheel instead of one, as at present. The new apparatus shortens the time of obtaining the maximum brake capacity from 8 seconds in the present system to 3½ seconds. With electric control, the time is shortened to 2¼ seconds. It was shown that a twelve-car steel train running 80 miles an hour could be stopped within 2,000 feet.

A Comparison of Broadsides.—Rear-Admiral Vreeland has filed with the House Committee on Naval Affairs a statement showing that in total muzzle energy of one broadside, the dreadnoughts of the German navy are twice as strong, in the aggregate, as the American dreadnoughts. In pre-dreadnought ships, the United States shows a heavier total muzzle energy than Germany; but combining both dreadnoughts and pre-dreadnoughts the total muzzle energy of the German fleet is stronger than that of the American fleet in the proportion of 11 to 8.

American Manager for English Railroad.—The appointment of Mr. Henry Worth Thornton, General Superintendent of the Long Island Railroad, as General Manager of the Great Eastern Railway Company in England, has been well described as "a personal compliment to Mr. Thornton, and a profound appreciation of American railroads and their men." The appointment has raised the inevitable "tempest in a teapot" in the British daily press. As a matter of fact, the appointment does credit to the judgment of the directorate of the Great Eastern Railroad, which handles the heaviest suburban passenger service into and out of London. Mr. Thornton will look at the problem from new standpoints, and with the advantage of a wide and varied experience.

Science

Soundings in Lake Tanganyika.—Recent soundings in the great African lake by Capt. Jacobs, of the German Navy, showed a maximum depth of 4,190 feet. Still greater depths are reported to have been found by a Belgian official. Accordingly Tanganyika is, with the exception of Lake Baikal, the deepest body of fresh water in the world, and further investigations may prove it to be even deeper than Baikal. In the deepest places thus far found, its bottom is at least 1,600 feet below sea-level.

An Aerial Tramway Across the Andes.—Work has been begun on a remarkable steel ropeway, 37½ miles long, which will serve as an extension of the railway from Ladorada to Mariquita, in Colombia, carrying the line over the Andes at an altitude of 11,000 feet. The steel rope is to be supported on a series of steel towers, from 40 to 125 feet in height, and will consist of 12 sections, at each junction point of which a motor will be installed of sufficient power to work two sections. Power is to be furnished by water brought down from the Andes.

Pili Nuts, which grow abundantly in the Philippines, have recently been shipped on a considerable scale to the United States. They are produced by trees of the genus Canarium, to which belongs the Java almond, are nearly triangular in cross-section, and contain a small oily kernel of almond-like flavor. Besides being very palatable in their natural state, they yield a valuable oil, resembling oil of almonds. According to an official report, the production of pili-oil is one of the coming industries of the Philippines, only awaiting the invention of a machine for cracking the nuts, which are very hard.

The Alaska Reindeer Service.—The latest report on this service, just published by the U. S. Bureau of Education, shows that on June 30th, 1912, the total number of reindeer was 38,476, distributed among 54 herds. Of these animals 62.5 per cent are owned by 633 natives; 9.8 per cent by the United States; and 16 per cent by Lapps. At an average value of $25 a head, the reindeer owned by the natives represent a capital of $601,700. The income of the natives from the reindeer industry during the fiscal year, exclusive of the value of meat and hides used by the natives themselves, was $44,885.04. The total number of natives affected by the reindeer enterprise is estimated at about 6,500.

Standard Tests for Hemp.—According to a report from the American consul general at Hongkong, the Fiber Division of the Bureau of Agriculture at Manila is conducting extensive experiments for the purpose of establishing scientific standards for testing hemp, in lieu of the present methods according to which experts, of many years' experience, judge the quality and value of the product by sight and touch. The new tests will be based upon the relation between the weight of a meter length of the fiber and the breaking strain. Tests for single fibers will be varied with tests for twisted fibers. As soon as this system of tests is fully worked out it will be put into effect in the Philippine hemp market.

Molecular Equilibrium.—O. Lehmann describes a method to determine the elastic limit of a viscous amorphous body. The application of this method to crystalline substances becomes complicated and the phenomena observed can only be explained on the molecular hypothesis and constitute a new proof of this theory. In liquid crystals the molecular equilibrium is related not only to the structure, but also to the form. The molecular equilibrium may be deranged by mechanical forces or by easily graduated magnetic forces. The strong surface tension, for example, produced at the boundary of the air and liquid crystals is able to derange the disposition of the molecules. The molecular perturbations produced by foreign substances able to form crystals mixed with the liquid crystals are the most striking.

True History of the Tepary Bean.—A brief note on the history of the tepary bean published in our science column of June 28th, 1913, and based on a supposedly reliable abstract in a foreign journal of an article by Prof. R. W. Clothier, of the University of Arizona, contained some inaccuracies to which Prof. Clothier has been good enough to call our attention. It appears that the tepary beans were originally found among a lot of beans obtained from the Papago Indians by Director Forbes, of the Arizona Experiment Station. They were tested independently by Prof. Clothier and Director Forbes, at places 400 miles apart, neither seeing the crop grown by the other. Both investigators recognized that they had fallen upon a valuable addition to the crops adapted to the Southwest, and both submitted the beans for botanical identification to Prof. G. F. Freeman, of the Arizona station. During the summer of 1910, Director Forbes and Prof. Freeman visited the Papago Indians in order to seek further information concerning the origin of the beans and secure other varieties. Prof. Clothier has never visited these Indians. The outstanding fact is that Director Forbes and Prof. Clothier are both entitled to the credit of introducing a valuable new crop to the attention of the world.

Aeronautics

A Flight from Cairo to the Cape of Good Hope.—Marc Bonnier, who recently completed a flight from Paris to Cairo, has announced his intention of flying from Cairo to the Cape. The trip may take two months and will be made under the auspices of the National Aero League.

An Optical Telegraph for Flying Machines.—A very interesting optical telegraph was recently tried out at the Breguet aerodrome, near Velizy. The apparatus consists essentially of a tube mounted in the direction of the flying machine's travel. The blast of the aeroplane's propeller is caught by this tube. Hence the tube is traversed by a violent current. Connected with the tube by means of a valve is a small reservoir filled with lampblack. By opening or shutting the valve, puffs of lampblack of greater or lesser duration are produced. It is said that these puffs can be seen through powerful field glasses, for about ten miles, and that a message in puffs projected according to the Morse code can easily be read.

New German Military Zeppelins.—The Zeppelin L. Z. 22 has just been completed at Friedrichshafen. It is intended for army use and will bear the number Z VII. It will be stationed at Dresden, where a new shed is in course of construction. Another Zeppelin Ll 23, is fast nearing completion. It, too, will be taken over by the army, so that the German military Zeppelins will soon number eight. In the Z VII. some important modifications from the standard Zeppelin construction are embodied. In order to avoid a repetition of the frightful disaster sustained by the L II. last December at Johannisthal, the cars in which the engines are contained are hung somewhat lower, with the result that the air may circulate freely between the envelope and the cars. It is said that Count von Zeppelin has definitely abandoned the idea of running the saloon or passageway which connected the two cars in Zeppelins, within the envelope itself as was the case in the L II.

Surgical Work of Aeroplanes in War.—Several interesting suggestions as to the uses to which aeroplanes might be put by the medical services in time of war were made by Lieut. Colonel J. D. F. Donegan, R.A.M.C., in the course of a lecture at the Royal United Service Institution, Whitehall. As regarded the use of aeroplanes for scouting for wounded on the battlefield, he could not at present realize their element of utility, but it was possible that at some future date aerial transport would simplify the duties of administrative medical officers on the field. The late Colonel Cody was deeply interested in the question of the provision of surgical assistance. From experiments made with both his machines, Colonel Cody and others were confident that it was perfectly possible to carry for long distances a specially designed operating table, with all surgical contents, and an operator, an assistant, and an anæsthetist, in addition to the pilot. Passing to consider the feasibility of his proposals, the lecturer explained that they were not for to-day or to-morrow. It would be quite time enough to consider the matter seriously when we were in possession of machines with the lifting power necessary to convey three officers, in addition to the pilot, provided that they were not at present available or in course of construction. The question of opposing forces objecting to aeroplanes engaged in medical work flying over their positions might be arranged amicably.

Fire-Proofing Aeroplane Fabric.—The object of fire-proofing a fabric of any kind is not the prevention of the charring or burning of the material but the prevention of the spreading of the flame which comes in contact with the fabric at any spot. It is better, therefore, to use the word "flame-proofing." For the flame-proofing of fabrics in general, there are two methods used, according to P. W. Litchfield, factory manager of the Goodyear Tire and Rubber Company. First, the impregnation of the fabric and the coating of the same with a non-inflammable mineral constituent, which must be either fused or mechanically broken away before the fiber can burn. Second, the presence of some salt, which, in addition to the above action, will give off some gas such as carbon dioxygen that displacing the oxygen, will prevent further propagation of the flame. There are three or more ways of carrying out this impregnation, one being the simple impregnation of the fiber with the mineral constituent as such; or, second, the use of such substances as glue, starch, dextrin, etc., as an adhesive for retaining the mineral constituent on the fiber, by first treating with a solution of such a compound as soluble phosphate, and then immersing in a bath of alum, whereby the insoluble aluminum phosphate is formed in the fabric. Coming to the fire-proofing of balloon fabric, it is more difficult because of the usual presence of rubber, which gives a new factor to the proposition. Here, perhaps, the presence, in the coating of compounds which liberate non-inflamable gases is more suitable than heavy loading of the fabric with mineral constituents which would increase the weight of the fabric and therefore be out of the question. There is, however, a difference in various rubber compounds as to the rapidity of flame spreading, due to the properties of the rubber itself and to the compounding and vulcanization.

An Ingenious Instrument for Studying Vibrations

The Bourlet-De Guiche Vibrometer

By Jacques Boyer

THE Bourlet-De Guiche vibrometer is designed for the purpose of registering the frequency and amplitude of the vibrations or oscillations of solid bodies which not only vibrate, but also move in any manner in space. Among such bodies are the frames of automobiles in motion (Fig. 4) and the wings of aeroplanes during flight.

The ordinary registering instruments, which require fixed points of support in the vicinity of the vibrating bodies, are not suited to these cases, in which the registering apparatus must participate in the general motion and select the vibratory movement for registration.

The Bourlet-De Guiche vibrometer, which its inventors recently submitted to the Paris Académie des Sciences, solves the problem in a complete and satisfactory manner. The apparatus comprises two manometric capsules, connected by a rubber tube. To the flexible membrane of the first capsule, or receiver, is affixed a large and heavy metal disk. This capsule, which is attached to the vibrating body, with its membrane perpendicular to the direction of vibration, participates in the vibratory movement without appreciably affecting it, because the mass of the capsule is very small in comparison with that of the vibrating body, while the inertia of the metal disk impresses upon the membrane a relative and inverse vibration of the same *period as that which it is desired* to register. The variations of pressure thus produced in the receiving capsule are communicated through the rubber tube to the second, or registering, capsule, which resembles an ordinary Marey capsule, and is provided with a stylus that writes a trace of its movements on a rotating cylinder coated with lamp-black.

A summary calculation shows that the relative motion of the disk with respect to the receiving capsule is compounded of a principal vibration synchronous with the vibration to be registered, and a secondary vibration due to the elasticity of the membrane. MM Bourlet and De Guiche have constructed their vibrometer in such a manner that this secondary movement is entirely negligible. For this purpose they employ a thick, tightly-stretched membrane and a metal disk large enough to cover the whole of the membrane except a narrow annular margin. In these conditions calculation shows that, for a given frequency of vibration, the amplitude *a'* of the oscillations of the tracing point varies in proportion to the amplitude *a* of the vibrations which are to be measured, but that the ratio between these two amplitudes is a decreasing function of the frequency.

The following theoretical deductions have been confirmed by experiment: 1. The secondary vibration is absolutely negligible and usually imperceptible, so that the synchronism of the tracing point with the vibration to be measured is assured. 2. For given frequency the ratio between the amplitudes *a* and *a'* (the ratio of damping) remains constant when *a* varies. 3. This damping effect increases with the frequency.

Before the vibrometer can be used on a vehicle it must be calibrated in the laboratory. The calibrating apparatus (Fig. 1) consists essentially of a metal rod *AB*, fixed at the end *A* and kept in vibration by means of an electromagnet *E*. The receiving capsule *R* is attached to the free end *B* of the rod which [illegible] upon it a regular vibratory motion. The rod carries a sliding weight *C* by means of which the period of vibration can be altered, and the amplitude can be regulated by turning the screw *D* attached to the interrupter of the electromagnet. The vibrations of the rod are registered directly by a stylus on the cylinder *F* which is turned by the clockwork *H*. The whole apparatus, including the vibrating rod, the electromagnet and the cylinder with its clockwork *H* and its support *S*, is mounted on a horizontal bar *MN* of square cross-section, which can be turned about its axis in order to place the receiving capsule *R* in a horizontal or a vertical position at will.

The registering capsule *I* and cylinder *K*, with the clockwork that drives the latter, are shown in Fig. 2. When the cord *AB* is cast loose the lever *ADC* turns about *D* and the clockwork is released by the withdrawal of a stop attached to the end *C*. The clockwork runs light for a few seconds until the helicoidal clutch, which can be seen in the engraving beneath *C*, has become completely engaged. This device avoids irregularity in starting and assures uniform rotation of the cylinder.

Fig. 3.—Calibrating the vibrometer.

Fig. 3 illustrates the method of conducting a calibrating experiment to determine the damping ratio as a function of the frequency of vibration. After the receiving capsule has been attached to the calibrating rod and connected with the registering capsule by the rubber tube, the rod is set into vibration and both cylinders are started. In this way the vibrations of the rod and of the membrane of the registering capsule (and, if great precision is required, those of a tuning fork also) are registered simultaneously. The experiment is repeated many times, the amplitude of vibration of the rod being varied by means of the regulating screw and its period being changed by moving the sliding weight. The records made on the cylinder *K* (Fig. 2) give the period of vibration, either from the known rate of rotation of the cylinder or by comparison with the tracings of the tuning fork. Then, after comparison of the records on the two cylinders has proved that the amplitude of the registered vibration bears a constant relation to that of the original vibration, or the same frequency, this ratio is measured for various frequencies, and the measurements are incorporated in a curve or a table, from which the value of the ratio for any frequency, or period of vibration, can easily be deduced. The calibrated vibrometer may be used for measuring the vibrations of any moving body, and especially of automobiles and aeroplanes.

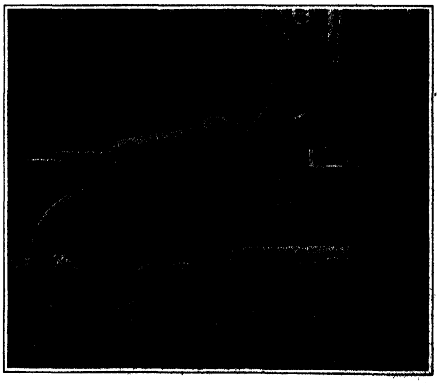

Fig. 4.—Measuring the vibrations of the chassis of a moving automobile by means of the Bourlet-De Guiche vibrometer.

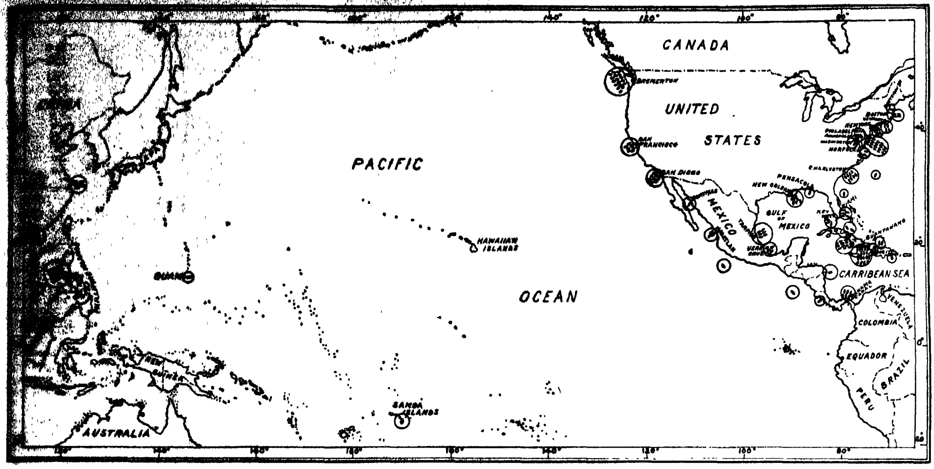

Map showing disposition of ships of the United States Navy on February 12th, 1914.

The Problem of Our Navy

I.—How the Navy is Daily Employed

By Hon. Franklin D. Roosevelt, Assistant Secretary of the Navy

> *Modern naval wars start with all the surprise and destructive shock of an explosion of dynamite, as witness the Japanese destroyer attack which so seriously crippled the Russian fleet at Port Arthur before any declaration of war had been made. Modern naval wars are won when the battleship fleets meet and fight it out to a finish on the high seas; as happened later when Japan annihilated the Russian first line of battle at Tsushima. The navy of a great nation like the United States must be proportioned to the magnitude of that nation's international policies—to the distance from home and the area of the field in which it may be engaged in hostilities—and above all, to the size and strength of the first battleship line of those nations which may dispute by armed force that nation's policies. As matters now stand, the United States is endeavoring to support first-class policies with a third-class navy. Measured by the daring of our policies and the boldness with which they are being proclaimed, our fighting line of dreadnoughts is about one half as powerful as it should be. The navy, as it stands to-day, is short of men, short of torpedoes, has no comprehensive scheme of swift mobilization—has, in fact, no adequate reserve of men with which to mobilize; and in case of sudden complications with a foreign power over, say, the Monroe Doctrine or the Panama Canal, would find itself incapable of entering into a war with any hope of that quick success, which will be achieved by the nation that engages with a preponderance of dreadnought strength and the ability to mobilize its whole fleet in a week or ten days' time.*
>
> *These are some of the questions which we shall consider in the series of articles on "The Problem of Our Navy," of which this is the first.*
>
> *But the Navy, though deficient in quantity—in ships, officers and men—is absolutely first class in quality. That the nation is being well served, day by day, in these times of peace, is shown in the following very able article by the Assistant Secretary of the Navy.*—EDITOR.

A CERTAIN person of some prominence in public life, who should have known better, recently referred to the American Navy as an organization of "highly paid idleness."

In regard to the pay of the Navy, it is sufficient to dismiss the allegation with the statement that the average pay of all the officers and enlisted men in the service amounts to just $618 per annum apiece. But the use of the word "idleness" leads me to fear that there must be some people who are not familiar with the manner of occupation of the ships and men of the service in times of peace.

In my office in Washington hangs a map of the world, showing by means of pins the location each day of the ships of the Navy. This map is a constant source of interest and surprise to visitors, and any study of it leads to the inevitable conclusion that our vessels and the men who man them lead an existence of constant occupation and useful effort, that is surpassed by no other agency of the Government of the United States.

It so happened that on the 12th of February, 1914, all the ships of the Navy, with the exception of a small gunboat used as a station ship at Constantinople, were located between the longitude of Santo Domingo on the east and that of Canton on the west. Therefore the appended map includes only that portion of the earth's surface. It should be remembered, however, that only a few months ago we had battleships in the Mediterranean, cruisers in South American waters and in other places not shown on this map, and that it represents only the locations shown on the Department map on the day it happened to be copied for reproduction in the SCIENTIFIC AMERICAN. Every day of the year the pins are changed as the ships move on their never-ending duties.

Some of their occupations are self evident; but a short explanation of why each ship is in each particular place will perhaps in itself give a better answer to the question, "Why have we a navy?" than would a dozen long volumes on sea power or strategy. For the accompanying map shows both the strength and the weakness, the sufficiency and the crying needs of the American Navy to-day.

Starting with the Asiatic fleet, there are shown five light draught river gunboats on the Yangtse River in China and two near Canton, all of them used on a friendly patrol duty which has been going on for many decades.

To the southward concentrated in the Philippine Islands is the main body of the Asiatic squadron, consisting of the following vessels: Cruisers "Saratoga," "Cincinnati," "Galveston;" monitors "Monterey," "Monadnock;" 1 gunboat; 5 torpedo boat destroyers; 6 submarines; 4 auxiliaries—a total of 21 vessels which in time of peace is sufficient to guard the various American interests in the island and other parts of the Far East, but which in time of war against any important naval power would be practically a negligible quantity. For it goes without saying that cruisers, old monitors, and a few destroyers and submarines could not long withstand an attack by a modern battle fleet. The maintenance of these ships of small fighting value in the Far East is justified not as a war measure, but because American activities, not only in our own possessions but in all the neighboring seas and countries, require in time of peace the moral support of the ships' presence.

Moving eastward on the map our next vessel is seen at the island of Guam, serving as a station ship for the island government, which is conducted with conspicuous success by a naval officer. In fact, a comparison of conditions on that out of the way speck in the Pacific with those existing before American occupation, or even with those existing to-day in nearby islands under the rule of another power, shows a real accomplishment of which the Navy and the American people can be proud. The same statement can be made about our other Navy-governed possession of Tutuila, or American Samoa. Here also a gunboat is maintained as a station ship.

Turning now to the northern Pacific, it will be seen that no ships are stationed at Hawaii This is however, only a temporary condition, and the completion of the Pearl Harbor Naval Station will make this an important strategic base.

In Puget Sound is located the Pacific Reserve Fleet consisting of the following ships battleship, second line, "Oregon," armored cruisers "South Dakota," "West Virginia," "Colorado," cruisers "Albany," "Charleston," "Chattanooga," "St Louis," "Milwaukee;" 2 submarines; 5 auxiliaries These ships are maintained with skeleton crews, and while still serviceable in battle against enemies' ships of equal age, would have small military value against a more modern fleet. In addition to these, a submarine recently completed is being placed in commission at Puget Sound

In San Francisco Bay are the cruisers "Cleveland" and "Marblehead" (in reserve); 1 gunboat; 4 submarines; 4 torpedo boat destroyers (in reserve); 2 torpedo boats (in reserve); 2 auxiliaries. It may here be noted that the necessity for the presence of ships in Mexican waters and for other important duties makes it highly undesirable to keep so many ships on the Pacific Coast in reserve, but the lack of sufficient officers and men to place them in full commission makes any other course impossible; and this in spite of the fact that the quota of men allowed is at present up to the legal limit.

Near Santa Barbara and San Diego, California, 5 torpedo boat destroyers with a parent ship are engaged in their annual maneuvers and torpedo exercises Two submarines with an attendant monitor are also engaged in their practice drills in this vicinity, and the armored cruisers "Maryland" and "California" are holding their usual winter target practice All of this work corresponds to the drills of the Atlantic fleet in West Indian waters each winter, but the shortage of men and the unusual international requirements have of late prevented the carrying out of these exercises in the manner the Department would like to see.

Farther south on the west coast of Mexico are found the armored cruiser "Pittsburgh," cruisers "Raleigh" and "New Orleans," 1 gunboat and 1 auxiliary. The reasons for their presence in these waters require no comment.

Still farther south the cruiser "Denver" is proceeding to relieve the transport "Buffalo" at Corinto, Nicaragua, where for some time the State Department has considered the presence of an American warship desirable. This completes the list of ships in the Pacific Ocean. They seem formidable in numbers, and they are doing valuable work of almost every conceivable kind, but as a fighting force against a modern fleet they must not be highly estimated

In the Atlantic Ocean is found both the greatest numerical and the chief military strength of the Navy. Far to the north in the Gulf of St. Lawrence, but not shown on the map, the naval tug "Potomac," bound on an errand of mercy to rescue the crews of American fishing boats, has herself been caught in the icefloes and at this writing is in grave danger of destruction. At Portsmouth, N. H., the cruiser "Tacoma" is undergoing repairs. At Boston the second line battleship "New Jersey," recently from Mexico, is being overhauled; the armored cruiser "North Carolina" and the cruiser "Chicago" are in reserve, and a new submarine is being placed in commission. At Newport 4 old torpedo boats are maintained in reserve and a submarine is being fitted out.

At New York the first line battleship "North Dakota" is repairing; the first line battleship "Arkansas" is in quarantine with a few cases of illness on board; the armored cruiser "Washington" is used as a receiving ship; a gunboat is in reserve, and a monitor and submarine are preparing for the formation of a new submarine division.

At the Philadelphia Navy Yard are the cruiser "Montgomery," 2 destroyers in reserve, and a submarine fitting out; and here also are stationed the ships of the Atlantic Reserve Fleet, as follows: Second line battleships "Idaho," "Maine," "Missouri," "Alabama," "Illinois," "Kearsarge," "Kentucky," "Wisconsin," "Indiana," "Iowa," "Massachusetts;" the armored cruiser "Tennessee," the cruiser "Salem" and repair ship "Panther" As in the case of other ships in reserve, they are from the military point of view valuable for fighting purposes only against ships of an equal or greater age. That it would amount to little less than murder to send American officers and men out in these old ships to fight against a fleet of modern dreadnoughts is a simple truth that everyone should understand. These ships have still a possible use; but to place reliance on them in a time of crisis could never be warranted

At the Naval Academy at Annapolis are stationed 5 torpedo boats, and at Washington two converted yachts. In the Norfolk Navy Yard the second line battleship "Vermont" is undergoing repairs to the shaft broken while returning from the Mediterranean, and the monitor "Tallahassee" is being used for ordnance experiments Off Cape Hatteras the first line battleship "Michigan" is proceeding south to join the other ships of the second division at Guantanamo.

Charleston, S. C., is the regular base of the torpedo boats and destroyers in reserve, but only 5 of the former and 3 of the latter, together with 1 submarine, are there at the present time. The rest of the reserve destroyers, 6 in all, are on the coast of Florida engaged in their annual practice cruise for a period of two months These vessels are manned by only half crews, but are kept on the whole in an efficient condition and are not obsolete At Key West three new destroyers recently placed in commission are engaged in "shaking down" trials and in torpedo practice preliminary to taking their places with the Atlantic fleet In Pensacola Bay the second line battleship "Mississippi" is being used in experimental aeronautic work At New Orleans the monitor "Tonapah" and the second submarine group of 5 vessels are engaged on the annual practice cruise.

Off the north coast of Cuba the "Prairie" and "Hancock," transports, are returning with two regiments of marines from a month of "advance base" maneuvers on the island of Culebra, just east of Porto Rico. This work consists, as the name implies, in landing and fortification drills with the object of establishing a base on a hostile shore

South of Cuba all the ships of the Atlantic fleet, except those in Mexican and Haitian waters, are engaged in the regular winter practice work—fleet and division drills, torpedo and target practice, boat drills, etc. At Guantanamo Bay are the following ships: Second line battleships "Louisiana," "Kansas," "New Hampshire;" cruiser "Birmingham," 1 gunboat and 12 torpedo boat destroyers.

A little farther to the west, near Guacanaybo Bay, Cuba, are the rest of the ships of the Atlantic fleet, engaged in similar practice: First line battleships "Wyoming," "Delaware," "Florida," "Utah," 6 torpedo boat destroyers, and one destroyer tender.

The island of Haiti has recently required the almost constant presence of one or more American ships. At Santo Domingo city is the gunboat "Petrel." Off the coast of Haiti are the battleship "South Carolina," the armored cruiser "Montana," the cruisers "Nashville" and "San Francisco," and the surveying ship "Eagle." The "Montana" was engaged in torpedo training exercises and the "San Francisco" in mine laying practice off the Cuban coast, but both were hurried to Haiti on the outbreak of the revolution there.

On the east coast of Mexico, performing an obvious duty, are the following ships: At Tampico: Second line battleships "Rhode Island," "Georgia," "Nebraska," "Virginia," cruiser "Des Moines;" and 1 gunboat. At Vera Cruz: Second line battleships "Connecticut," "Ohio," "Minnesota," and cruiser "Chester." Off the coast of Honduras the auxiliary "Hannibal" is engaged in hydrographic surveying. Finally, at Cristobal, the Atlantic end of the Panama Canal, are 5 submarines and their "mother" ship the gunboat "Severn."

I regret that it is impossible in this short article to describe in detail the daily life of the officers and men on board all these ships in both oceans Ask any of them and they will tell you that there are few moments for idleness, that the many duties require constant mental alertness and physical fitness, and that the man who wants to succeed has in the service to-day a field of opportunity greater than ever before.

Such was the disposition of the American Navy on the 12th day of February, 1914. Briefly, it shows that in times of peace it is as an organization very much occupied with many different kinds of work in many different places; that it is keeping the peace, preventing bloodshed and disorder, governing islands, carrying on scientific work for the benefit of commerce, seeking to rescue castaways, and doing daily a hundred unsung deeds that make it an American institution to be proud of.

But there are other facts to be deduced also—facts based on the premise that the primary object of the Navy is to be ready in the unfortunate event of war To this end all others must of necessity be subordinated. Just as the police force of a city is of little value in stopping the invasion of a country by a foreign force, so the work of the gunboats and surveying ships and obsolete battleships in time of peace would count for little against the enemy's fleet in time of war. The day is past when it was possible to build, equip and man a frigate in six months. Now a battleship which takes three years to build cannot be taken into an engagement by any kind of officers or any kind of a crew. Many months of thinking, toil and practice are necessary to efficient maneuvering and straight, quick shooting.

A naval war of to-day would not see single ships in action, nor would it see a fleet divided and scattered along the two coasts of the continental United States. A glance at the map shows a part of our activities and interests outside of this continental portion in time of peace. Would we then in time of war be content like the turtle to withdraw into our own shell and see an enemy supersede us in every outlying part, usurp our commerce and destroy our influence as a nation throughout the world?

Yet this will happen just as surely as we can be sure of anything human, if an enemy of the United States obtains control of the seas And that control is dependent absolutely on one thing—*the preponderant efficiency of the battle fleet.* A thousand gunboats, a thousand harbor-defense submarines or monitors would avail us nothing. Invasion is not what this country has to fear. If the American people are willing to be relegated to the position of a nation unimportant in the great affairs of the world, without influence in commerce, or in the extension of peaceful civilization and high ideals throughout the world, they need no battleships, they need not fear the loss of control of the seas.

Students of naval warfare, naval officers, historians, are as a whole as desirous of peace as any class of Americans; they deplore the struggle of the nations to guard themselves with military preparations, but they realize that we are confronted with a fact and not a theory. The day will come, they hope, when armaments will be limited by international agreement, and they are ready to help hasten that day. But until that day is an assured fact the American Navy must keep the principles of a possible naval conflict always in mind. The efforts of all must be concentrated, as far as possible, on the preparation of the battle fleet. That fleet must at all costs be kept together, for division of forces is fatal; it must be drilled and maneuvered; it must spend good money for target practice; it must contain the best material and the latest devices; and it must in its personnel typify the highest ideals, the greatest efficiency of American citizenship.

Sir David Gill

SIR DAVID GILL, the eminent astronomer, died in London on January 24th in the seventieth year of his age. He was educated at the University of Aberdeen, and spent the time between his twenty-fifth and thirtieth years in preparing himself to be an [illegible] at a private observatory in Aberdeen. During [illegible] three years, 1873 to 1876, he directed the [illegible] servatory of the late Earl of Crawford, then [illegible] say, and organized the Lord Lindsay [illegible] Mauritius to observe the transit of Venus, [illegible] vations being undertaken with a view to a [illegible] tion of the distance of the sun, a problem [illegible] a lasting interest for Sir David, and to which [illegible] constantly returning.

From the measurement of the distance of the [illegible] turned to the measurement of the earth. [illegible] same three years he connected the longitudes of [illegible] Malta, Alexandria, Suez, Aden, Seychelles, [illegible] and Rodriguez, and measured the baseline [illegible] geodetic survey of Egypt, near Cairo. This [illegible] first step toward realizing what he called the [illegible] his life, namely, the measurement of the great [illegible] arc of the earth on the thirtieth meridian.

In 1880 he proposed the geodetic survey of [illegible] Cape Colony, although the project was not [illegible] completion till sixteen years later. He lived [illegible] gap in the arc between Rhodesia and the [illegible] up and its subsequent extensions through [illegible] Africa, along Lake Tanganyika, toward the [illegible] When that work is altogether completed the [illegible] will join that of Greece and Struve's great [illegible] terminates at the North Cape, and will be the [illegible] length of the world's surface, 105 deg., more [illegible] miles, to be measured with mathematical accuracy.

But before this, in 1877, he proposed and carried out an expedition to Ascension Island to determine the solar parallax by observations on Mars, and in [illegible] he was offered the post of Astronomer Royal at the Cape of Good Hope. He continued his work along the lines of solar parallax determinations, organizing transit of Venus expeditions to this end.

In 1882 a great comet became visible, and Sir David, with the assistance of an intelligent Cape photographer, succeeded in obtaining some beautiful pictures of the comet, the camera being strapped on the telescope, and not only of the comet, but of the surrounding stars. They were the first really fine photographs of a comet, but they were also the first of the modern photographic star-plates, and from these photographs sprang the whole project of the great Star Map, which still engages the observatories of the world. From this also originated the new method of determining the sun's distance by photographic observations of the minor planet Eros. The spirit which inspired Sir David Gill in his work is best described in an extract from his presidential address to the British Association in 1907:

"Accurate and minute measurement seems to the non-scientific imagination a less lofty and dignified work than the looking for something new. But nearly all the grandest discoveries of science have been the reward of accurate measurement and patient long-continued labor in the minute sifting of numerical results."

He was the recipient of numerous honors, among others being the F. R. S. and K. C. B.

International Map of the World

THE second international conference on the "millionth" map of the world (Carte internationale du monde 1: 1,000,000) met in Paris, December 10th to 18th, 1913, and was attended by representatives of thirty-four countries. Although the fundamental features of this chart were settled at the original conference, in London, many special problems have arisen, and these the second conference attempted to solve. Specimen sheets of the chart have already been prepared by Great Britain, France, Spain, Italy, the United States, Japan, Mozambique, and Sweden. At the London meeting it was decided to include on the chart place-names in common international use in addition to the official names used in the several countries. The Hungarian delegation at Paris endeavored unsuccessfully to have all but the official names eliminated. In the discussion on this subject Prof. Partsch pointed out that the world at large would hardly recognize Jerusalem and Damascus under their official names of El-Kuds and Esh-Shâm, respectively. An additional argument in favor of retaining customary international names is that official names are subject to change with changes of sovereignty (as, for example, after the recent war in the Balkans). It was decided to establish permanent headquarters for the undertaking at London and Southampton. The next conference will be held in Berlin toward the end of the present year.

The "Limequat."—This portmanteau name has been applied to a new hybrid, obtained by crossing the West Indian lime with the kumquat. The tree is much hardier than the lime, having withstood the past three winters in extreme northern Florida, where the lime cannot be grown. Fruit was obtained for the first time during the past year, and proved to be much like the West Indian lime in size and flavor.

Possibility of Utilizing Power From the Sun

To the Editor of the SCIENTIFIC AMERICAN:

I read with much interest an article in your SUPPLEMENT of January 31st, 1914, entitled, "Energy Sources of the Future."

In this article you say: "The capture (of the sun's heat) has been attempted, but on a very small scale and by an ineffective method. The sun's rays have been made to furnish mechanical energy by generating steam in boilers. This method involves great losses, and is incapable of high efficiency."

We have experimented during the past seven years on a *very large* scale with sun power, and have brought sun power from the ideal stage into the real. Our sun power plant at Cairo has been tested by well known independent engineers, and inspected by many engineers and scientists. Lord Kitchener and Sir Reginald Wingate have watched its working and invited us to put up a similar plant in the Soudan.

Every figure I am going to give is based upon actual results already obtained. There is not a single "should give" or "guess" about it. Sun power is now a fact, and is no longer in the "beautiful possibility" stage. It can compete profitably with coal in the true tropics *now*.

Sun power has a history something like aerial navigation. Up to twelve years ago it was a mere possibility and no practical man took it seriously. The Wrights made an "actual record" flight and thereafter developments were rapid.

We have made an "actual record" in sun power, and we also hope for quick developments.

The steam boiler has had a hundred and fifty years time for evolution and has reached an efficiency during all this time of only 75 per cent at best.

Our method of generating steam from the sun's rays has had only seven years' time for evolution and has already reached an efficiency of 57 per cent.

Surely this, considering the youth of sun power, is not to be described as "incapable of high efficiency."

Our sun power plant of the vintage of 1911 turned 43 per cent of the heat of the sun which reaches the earth's surface into steam, and our present plant tested during the end of August, 1913, turned 57 per cent into steam, an improvement of 14 per cent in two years' time. This record should certainly encourage us in thinking that during the next ten years we shall be able to reach the 75 per cent efficiency of the best modern steam boiler, and thereafter possibly surpass it.

I will now give a few figures which I stand ready to prove from actual results, as to how safely the human race can lean on the heat and power from the sun's rays, when this heat is turned into steam (surely the most direct and logical way of utilising it).

These figures are based on the results actually secured at Cairo, Egypt, in latitude 30 degrees north, by no means yet on the equator, where results would still be better, and on what *has been done*, and not what is going to be done.

For the purpose of my calculation I have taken as a basis the figure given in your article of two hundred and seventy million horse-power continuously throughout the year being equal to all the coal and oil mined during the year 1909 throughout the world.

Now, our sun heat absorbers at Cairo occupy less than an acre of room and develop 50 brake horsepower throughout a ten-hour day. This does not mean that an acre of sunlight is intercepted. The area of sunlight intercepted is only 13,269 square feet, or less than one third of an acre, but it is necessary to place the heat absorber units sufficiently far apart so that they won't shade each other in the early forenoon and late afternoon.

Taking the above actual work of our plant as a basis, it would only be necessary to cover 20,250 square miles of ground in the Sahara Desert with our sun heat absorber units, spaced as wide apart as they now are, to give *perpetually* the two hundred and seventy million horse-power per year required to equal all the fuel mined in 1909.

This area of 20,250 square miles is practically equal to a square of 143 miles, and its size as compared with the Desert of Sahara is shown by the accompanying map. Surely from this showing, the human race can see that sun power can take care of them for all time to come.

Now the next question your reader will ask is, "How much will it cost to do all this?" Of course the figure will be staggering, being equal to ninety-eight and one half billion dollars ($98,500,000,000).

An independent engineer with long experience in power plant building in the tropics, estimates the cost of construction and erecting the 50 horse-power sun heat absorbers referred to above at $7,600, and by ordinary proportion we obtain the figure given above. Surely this is safe, because in the hundred odd years or so required to totally exhaust our fuel store there will be great developments in sun power.

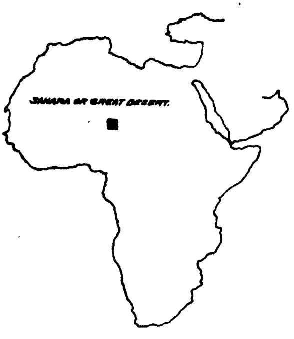
Having planted the desert with sun heat absorbers at a cost of ninety-eight odd billion dollars, let us look at what we have secured at this enormous cost, and let us see whether we have made a good investment.

We will then have a plant that is worth to us at least as much as all the coal and oil fields in the whole world; because it can *perpetually* give us as much heat and power as all of the coal fields and oil fields of the world put together, if mined at the 1909 rate. And these are certainly worth very much more than ninety-eight odd billion dollars.

This vast investment would not be made for or by the individual, but for and by the entire human race, and we may safely assume the human race to survive all the coal and oil fields by many thousands of years. Hence, its overwhelming value of perpetuity and its capacity for practically infinite expansion.

The wear and tear and depreciation of sun power plants is no greater than that of coal or oil consuming plants, and another advantage is that the heat is delivered into the boilers entirely free of all cost. All the tremendous costs of mining and transportation and dangers to life are avoided.

To the individual, ninety-eight billions is a staggering sum, but to the human race, particularly if spread out through a period of say 200 years, it is *almost nothing*.



This map shows how very little of the Great Desert of Sahara would have to be covered with sun heat absorbers to obtain *every year* a heat value equaling that of all of the coal and oil mined in all the world during the year 1909

The human race has expended in coal mines and oil mines and boiler and heating plants many times that sum during the last hundred years alone.

We feel sure the greatest developments in sun power will come when the minds of many thousands of thinkers will be turned in this direction, by the results of our work. We do not expect to do it alone, all we shall now do is to establish sun power as a commercial rival of coal in those portions of the true tropics where coal is very expensive and the sun is very powerful. This will result in enormously increasing the area of cultivatable land, and we will rest at this for the present.

One thing I feel sure of, and that is that the human race must finally utilize direct sun power or revert to barbarism, and I would recommend all far-sighted engineers and inventors to work in this direction to their own profit, and the eternal welfare of the human race.

Tacony, Philadelphia. FRANK SHUMAN.

The Four-cylinder vs. the Six-cylinder Car

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of January 3rd, page 10, under the heading "The Car of 1914" we find this statement:

> "The six cylinder car is predominant. From a small beginning it has swept on until in 1914 it has well nigh carried all before it. *It is the prevailing feature of the past automobile year* beside which other features pale; but not into insignificance."

We are inclosing a tabulation of the exhibitions at the recent auto shows in New York. While this does not necessarily settle the question, it is at least significant.

Your contributor made no distinction in his article; he bluntly said, "The six-cylinder car is predominant."

We feel at liberty therefore to answer it on the same basis.

While the number of makers producing "sixes" has probably increased by what may look like a big percentage, the increase in the actual quantity of six-cylinder cars produced is not relatively large.

There are at least two, and we believe four makers, any single one of whom is producing more four-cylinder cars than all the six-cylinder cars combined.

Now pardon us if we mention the Cadillac. We have already shipped more than 7,500 of the 1914 models.

We would not be surprised if this nearly equaled the output so far of all 1914 six-cylinder cars combined. It certainly exceeds the combined output so far of all six-cylinder cars which are generally recognized as being high grade or even those selling at or above the Cadillac price.

Taking the proposition as a whole, we find according to estimates which are as authoritative as such estimates can be, that the number of cars which have and which will be produced during the 1914 season will be eight to ten four-cylinder cars to one six-cylinder car.

On the basis of dollars and cents, these same estimates show that the selling value of the fours will be two to three times the value of all the sixes.

The fact is, the six does not even approach the four, whether you figure on the basis of the quantity of cars produced or the value of the product.

This letter is dated January 19th, at which time more than 7,500 1914 Cadillacs have been shipped.

Dividing United States Coins

To the Editor of the SCIENTIFIC AMERICAN:

I give herewith a solution of the problem in United States coins, given by Theodore L. DeLand on page 117 of your issue of February 7th:

22	coins of	$20.00	each	$440.00
4	" "	10.00	"	40 00
1	" "	5 00	"	5 00
4	" "	2.50	"	10 00
6	" "	.50	"	3 00
1	" "	.25	"	25
1	" "	.10	"	.10
1	" "	.05	"	.05
160	" "	.01	"	1.60
200				$500.00

New York city. FRANCIS J. HALL

To the Editor of the SCIENTIFIC AMERICAN.

In the correspondence column of your issue of February 7th, Mr. Theodore L. DeLand wants to know how two hundred United States coins can be divided so as to total five hundred dollars. Given below are three solutions:

(1)	6	$20.00	$120 00
	4	10 00	40 00
	10	5 00	50 00
	110	2.50	275.00
	16	.50	8 00
	18	.25	4 50
	22	10	2 20
	4	.05	20
	10	01	10
	200		$500 00
(2)	6	$20 00	$120 00
	6	10 00	60 00
	8	5 00	40 00
	110	2 50	275.00
	2	.50	1 00
	2	.25	.50
	20	10	2 00
	26	05	1 30
	20	01	20
	200		$500 00
(3)	2	$20 00	$40 00
	8	10.00	80 00
	10	5.00	50 00
	130	2.50	325 00
	2	50	1 00
	4	.25	1 00
	20	.10	2 00
	19	.05	95
	5	01	05
	200		$500.00

Kingston, N. Y. E A VIGNES

The Earthquake Felt at Troy

To the Editor of the SCIENTIFIC AMERICAN:

I write to report an earthquake at Troy, N. Y., on February 10th, which lasted from 1:30 P. M. to about 1:31 P. M. The quake was strong enough to cause loose articles to rattle and was distinctly noticeable to a person sitting down. The vibration was much like that caused by an engine on a boat.

Troy, N. Y. JOHN WILLIAM BACON.

A Triumphant Struggle With a Beetle

How the Cocoanut Trees of Samoa Were Saved

By H. J. Moors

THE value of cocoanut products has increased at a wonderful pace during the past five years, and the acceleration during the past two years has been quite phenomenal. This is chiefly owing to new methods of treatment and manipulation as applied to copra.

Cocoanut oil when made from the best materials is clear white and has a sweet, agreeable, nutty flavor. It is now possible to refine, clarify, flavor, and congeal this substance into a very useful butter, and numerous factories in Europe and also some in the United States have worked up such profitable business, that some of them last year declared dividends exceeding 40 per cent.

The demand for first-class copra is continuous and increasing, and the supplies though very large are still far below the demand, which every month enhances.

Many planting companies have been formed in Great Britain and in Germany, and very large groves of cocoanuts have been set out in many parts of the tropical world, but even if all of these were in fullest bearing, their output would hardly depress the market, so strong is the demand for this edible oil.

The cocoanut tree grows only from the mature nut, which is planted about six inches in the ground and not entirely covered up. Six years later the growing tree begins to deliver its fruits, a little at first, then more and more, until the twelfth year, when in good situations it delivers from 70 to 100, even up to 150 nuts per annum, each producing from one third to one half pound of dry copra.

About 50 nuts are planted to the acre and these give from one third to one half ton of copra which is worth to-day in the United States and in England about $160 per ton.

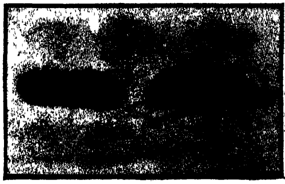
Fine grasses are grown beneath the trees in some parts, and great herds of fat cattle are raised for consumption.

As the cost of manipulating a cocoanut plantation is very little when it is in full bearing, and stocked with cattle, it can well be conceived that such property is highly valuable, and is held at prices ranging from $200 to $300 per acre.

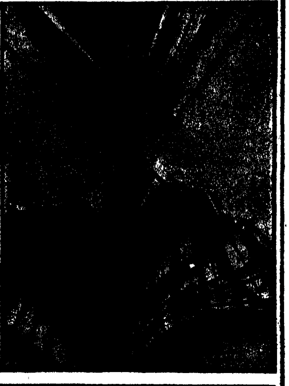
About 50 years ago, a vicious beetle appeared in Madagascar, and attacked the crowns of the trees, boring deep galleries right through the leaf stems into the heart of the cabbage. When these insects confined themselves to attacking the tree pretty high up, they did no very serious damage, though they ruined its graceful appearance. If they attacked low down, or deflected their course downward after entering, then they very frequently killed the trees. These insects range from an inch to an inch and three eighths in length; they are very thick and are armed with a formidable horn, from which they take their name.

Grove of cocoanuts taken from a balcony in *Apia. These were all in a fair way of dying,* but were saved by natives climbing them and removing the beetles with sharpened wires. Afterward the hunt for larvæ in this neighborhood become so keen that the trees were not attacked again.

Old cocoanut leaf branch, showing the tunnels through which the beetles entered.



Cocoanut or Rhinoceros beetle and larvæ.



Showing the beetles' work at close range.

Finis.

A TRIUMPHANT STRUGGLE WITH A BEETLE

They have done immense injury all over the tropical world, especially in Malaysia, Madagascar, Ceylon, the Philippines and Cochin China. About four years ago they first appeared in German Samoa, but little notice was at first taken of them. Later on, their destructive work attracted attention, and then alarmed the foreign residents.

Rewards were offered for the live beetles, and for their larvae, and after some $10,000 was paid out in a few weeks, the government had to change its policy, and to compel all natives to hunt beetles for about three hours each week for their own protection, while the foreign residents contributed liberally in cash for the abatement of the nuisance. Of course, such efforts had their effect, but the plague seemed to spread fast in all directions before the prevailing wind. In due course fully 20,000 trees were killed outright, and probably ten times as many are still beetle-infested and many will die.

The beetle lays its eggs frequently, and always on the ground, in the midst of rotting rubbish, if possible, rotting wood being a favorite place. It was found that if shallow pits were dug, say six by six, and a foot deep, and these filled up six or eight inches with rotten stuff, and a heap of cocoa shells piled on top, and the whole covered up with the soft soil that was first taken from the pit, a first-class beetle-breeding place had been provided.

It is likely that the smell of the fermenting and decaying cocoa shells drew the mother beetles from all directions. At any rate, they came to these "Tumus," and laid their eggs, and every ten weeks these "Tumus" were opened, and the larvæ and loose eggs were taken out and scalded. By this means probably millions of beetles never reached the harmful stage. These efforts were of great value, but something more was wanted, for the plague increased and many acres of fine cocoanuts were devastated. At last an experienced entomologist was sent for, and young Dr. Fredericks came out from Berlin. Month after month the residents of Samoa impatiently awaited results.

Feeling that more scientific help might perhaps find a way to limit the evil, private subscriptions were set afoot and Dr. Doane, of the Leland Stanford, Jr. University, was induced to come to Samoa during his summer vacation, and he and Dr. Fredericks worked in complete harmony.

But as Dr. Doane's stay was limited to seventy days, he had not sufficient time to do very much.

During the investigations, Dr. Fredericks noticed on one single beetle larva two small brown spots on its back; in a few days these coalesced and became one, and the larvæ sickened. Minute observation showed that it had been attacked by an island fungus. Other larvæ were confined with it, some twenty or more, and several of these were soon infected. But for many weeks the

"White Art" and the Automobile Leap at the Hippodrome

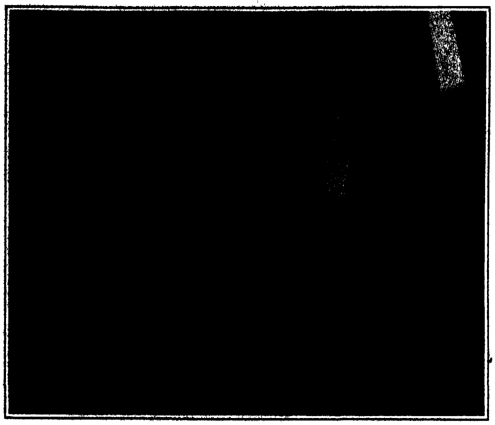
Phosphoresence by Irradiation

THE New York Hippodrome far outclasses its London namesake, and in the past nine years nearly 27,000,000 people have passed its doors. Each year presents novelties which are of great interest, and on two other occasions we have shown some unique features. This year two new acts are given which are certain to interest all readers of the SCIENTIFIC AMERICAN. Through the courtesy of Mr. Arthur Voegtlin, who has been responsible for the remarkable scenic effects in this vast house for many years, we are enabled to present authentic pictures of "white art," posturing as we might term it, in contradistinction to "black art," where the actors are clothed in somber mantles and perform on a dark stage. We might go a step farther and call it "luminous white art," for the girls would not give the realistic ghost-like thrills when they walk down the aisles if they did not wear phosphorescent garments.

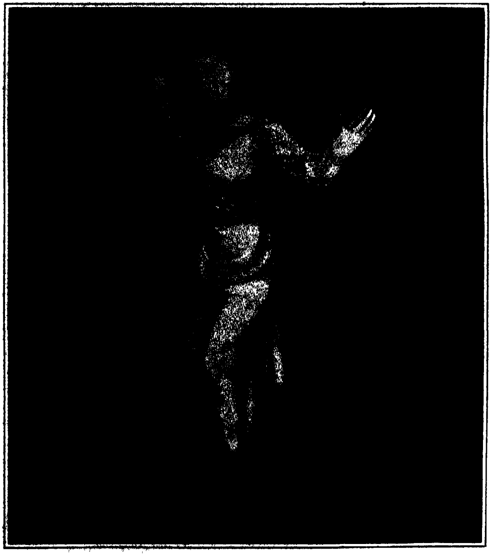
It might perhaps be well to glance for a moment at the principles which underlie all luminous preparations. A curious circumstance is that light from what we call phosphorus is not true phosphorescence at all, because it is accompanied by quite appreciable heat and is caused by slow combustion. It proceeds from the vapor of the phosphorus undergoing slow combustion. The term phosphorescence would best be applied only to cases in which no heat is appreciably evolved and no oxygen appreciably absorbed. The "luminous paint" phenomena belong to what is known scientifically as "phosphorescences by insolation or irradiation," giving out light in the dark after exposure to sunshine, the light of burning magnesium or the electric arc light. It appears that when certain rays of light fall upon a phosphorescent substance a change is caused and the rays are transmuted into others. In other words, the storage battery might be cited as a similar instance where chemicals are used to store up a potential force. The light which is stored in the phosphorescent substance is vitiated and in time exhausted when exposed in the dark.

In the Hippodrome during a "spooky" act the lights in the house suddenly go out and down the aisles come girls clothed entirely in white luminous garments, even to masks, headgear and gloves. They move up and down the aisles gracefully posturing like dancers to the mystification of the audience. People often put out their hands to touch the ghosts to see if they are real. After a minute or so the girls retire and assume their long black cloaks and they would hardly be noticed in the foyers. To be successful the house must be as dark as "Chevreul's black;" this is accomplished by the ushers momentarily masking the exit lights. The effect is most mysterious, as will be seen by our engraving.

A short time before the act the girls go to dressing rooms on the orchestra and balcony levels, and assume the luminous garments. Their faces are completely masked and they wear smoked goggles to protect their eyes while their garments are being charged. About 20 minutes are required to fully saturate the luminous coating. They turn around and bathe in the light so that every portion of their clothing is impregnated by it. Afterward comes the "cue" and the electrician turns off the switch and the girls move to their stations, where the ushers divest them of their cloaks, and they proceed down the aisles. It is a very pretty conceit and is exceedingly well done.



Charging the luminous garments with light emanations from an electric arc light.



"White art" weird ghost girls pass down the aisles dressed in phosphorescent clothing.

In the next scene we have the Grand Cañon of the Colorado River portrayed as well as it can be by the scene painter's art. The stage is divided into two parts by a great proscenium arch. To the front of this is the "apron" with its platforms covering the unique feature of the Hippodrome—the tank. While the tank is being filled, a short operation, the scene shifters are bringing out and lashing together three sections of roadway 79 feet long, which extends from the up-stage end to the edge of the tank. These elevated sections are strongly braced to stand the shock of the automobile in its spectacular descent. Mr. Voegtlin tried countless experiments with models before the exact angle of the track was determined. It was found by trial that the wheels need not be fixed and that the machine could be steered like an ordinary automobile.

Then came the call for volunteers for an actual test, for the use of dummies would have proved nothing. Finally one of the engineering staff, a man of extraordinary nerve, stepped forward and offered to pilot the machine With bated breath the technical staff waited to see whether he would land in the tank or in 6, 7 and 8. Fortunately he got clear and jumped at the right time and the trick was turned, but a new automobile was required for the next trip After about five automobiles were converted into junk, a special property auto was made of angle iron and it still stands the twice-daily ordeal. The run-way is banked so as to prevent the wheels leaving the track.

The car has weights secured in the back and there is a hump at the end of the track which serves to throw the car up so that it turns a complete somersault, landing in the water bottom side up. The tank is filled to 14 feet for this act and a tell-tale makes sure that the men will land in deep water when they jump The men swim under water and are seen on the surface as the curtain rises (it does not lower at the Hippodrome).

Some Well-packed Eggs

THE somewhat unusual feat of shipping eggs from one side of the world to the other was recently accomplished when a consignment from Russia arrived at Pittsburgh without a single one being cracked or broken. This shipment consisted of fifty cases, or 6,000 dozen, and originated at Warsaw The eggs were carried by boat to Labava, a distance of 1,400 miles, thence 1,500 miles by rail to Rotterdam, about 3,000 miles across the Atlantic to New York and 500 miles by rail to Pittsburgh The distance traveled was about 6,400 miles, and the eggs were drayed on a number of occasions, transferred from boat to rail and *vice versa* The cases were stood on end and with chains wrapped around three or four cases in a bunch they were lowered into the hold of the vessel and, in general, were subjected to much rougher handling than is encountered by shipments in this country

The cases in which these eggs were packed were 70½ inches long, 22 inches wide and 9½ inches deep, and were made of pine The ends were ⅞ inch thick and the top, sides and bottom ½ inch, the strips being 6 inches wide. In packing the eggs the case was laid flat and the packer took shavings and made a cushion, which was about 1 inch thick when packed close On top of the cushion the eggs were placed in 10 rows of 18 each, or a total of 15 dozen in each compartment layer. He then placed another cushion of shavings of the same thickness on top of this and then another layer of eggs, repeating the process until the filled case contained four layers. It is stated that the case and the shavings can be provided more cheaply than four of our standard cases with fillers of the same combined capacity.

A Monument to Capt. Robert F. Scott has been erected on the Col du Lautaret, France, in the Alpine garden of the University of Grenoble, where Scott spent some time mountaineering in 1908, in preparation for his Antarctic expedition. The monument is in the form of a polar cairn, ten feet in height, and bears a suitable inscription. It was erected by Scott's French admirers, on the initiative of Dr. J B. Charcot.

The Heavens in March

Is Interstellar Space Transparent? Are There Dark Nebulæ?

By Henry Norris Russell, Ph.D.

AMONG the recently published astronomical papers have been some of great interest which deal with the question whether interstellar space is transparent. We ordinarily assume that the light of the stars, even though it may have hundreds of years to travel before it reaches us, suffers no further loss in its passage than that which naturally arises from the spreading out of its waves over an ever-widening area. But within the last few years, this hypothesis (for it is no more) has been called in question by several investigators, and for different reasons.

If interstellar space was absolutely empty of matter, we know of no reason why light should be absorbed in passing through it; though he would be a bold physicist who claimed that we know enough about the ether to be sure that no such absorption could take place. But it is very improbable that interstellar space is so absolutely barren. There may be a good deal of matter floating about in it, perhaps in the form of solid lumps or particles of different sizes, perhaps as separate molecules of gas, and such matter, if it exists, would make the space within which it lay imperfectly transparent, acting like a very thin mist or fog.

The behavior of such absorbing material would, however, be different, according as it was composed of relatively large particles, or of material of molecular fineness. In the first case, it would absorb light of all wave lengths to the same degree as a dust-cloud in our atmosphere does; but in the second, it would absorb blue light much more strongly than red, like our atmosphere itself, whose absorption in clear weather is largely due to the scattering of light by the air molecules.

Within the last few weeks very convincing evidence in favor of the existence of absorption of both these kinds has been published. Prof. Barnard, following the same line of argument developed in earlier papers, calls attention to some of the remarkable black spots in the Milky Way. One in particular, in Sagittarius, appears as an oval patch, about half the apparent diameter of the Moon, in the middle of a dense star-cloud. All around it the stars strew the sky so thickly that on the photograph their images almost overlap; but within this small region there is blackness, except for two isolated stars. A mere glance at his photographs shuts one up to two explanations. either there is a hole through the star-cloud through which we see into the abysmal night beyond, or there is an opaque body in front of the star-cloud, which hides part of it.

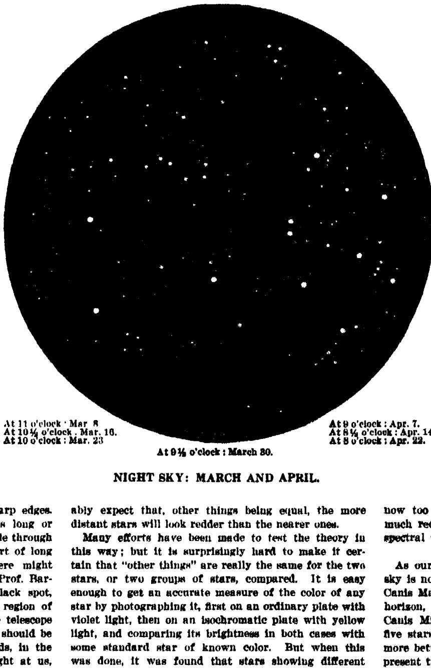
The chief difficulty about the first explanation is that the dark hole is very small compared with the cloud, and has sharp edges. If the star-cloud is about as thick as it is long or broad, which seems natural to suppose, the hole through it, to look as it does, would have to be a sort of long narrow tunnel, pointing right at us. There might perhaps be one such affair in the sky; but Prof. Barnard gives particulars of another similar black spot, equally dark, but still smaller, in the same region of the heavens, which, as he says, looks in the telescope "like a drop of ink in the sky." That there should be two such tunnel-like holes through star-clouds, in the same part of the sky, and both pointing right at us, passes belief

The alternative explanation offers no such difficulties; but the existence of huge and practically opaque regions in space, whose diameter may be a large fraction of a light-year, if not more, is so startling an idea that it needs a good deal of proving. But Prof. Barnard has greatly strengthened this idea by careful visual studies of the first of these dark regions with the great Yerkes refractor. On a clear night, with fine seeing, he finds that in this region the sky is "dull" compared with the surrounding regions, and that on one part of the area it is very faintly luminous showing that a very faint but real object occupies the place of the "dark hole" There are a number of other regions where "dark lanes" seem to be connected with visible nebulosity, but the new one is one of the most remarkable, and the evidence is now so strong as to convince most astronomers that regions of absorbing matter—"dark nebulæ"—probably exist between us and the Milky Way. The few isolated stars in the dark areas are presumably on the nearer side of the "dark nebulæ" which seem sometimes to be almost perfectly opaque.

But these absorbing regions, though almost incredibly huge, are isolated; and we can only detect them in case the great star-clouds of the Milky Way afford a luminous background on which they are projected. If the whole heavens were filled with a uniform haze of the same sort, making all the stars seem fainter than they otherwise would, we would be unable to detect it, because of its very uniformity.

The chance of detecting general absorption of this sort becomes much better, indeed, the problem only becomes soluble at all with our present means, when the absorption is of the second kind, increasing from the red to the violet. In the presence of such absorption, a star, if we could remove it to greater and greater distances, would look redder and redder, just as the sun does as it sinks in the west, so that its light has to traverse an ever-increasing thickness of air.

We cannot actually remove a star to varying distances; but, on the same assumptions, we can reasonably expect that, other things being equal, the more distant stars will look redder than the nearer ones.



NIGHT SKY: MARCH AND APRIL.

Many efforts have been made to test the theory in this way; but it is surprisingly hard to make it certain that "other things" are really the same for the two stars, or two groups of stars, compared. It is easy enough to get an accurate measure of the color of any star by photographing it, first on an ordinary plate with violet light, then on an isochromatic plate with yellow light, and comparing its brightness in both cases with some standard star of known color. But when this was done, it was found that stars showing different spectra were very different in color. So we must confine our investigations for the detection of "space absorption" to stars of exactly the same type of spectrum, and then must pick out near and remote ones for comparison of color. But we must choose stars of about the same apparent brightness, for a long exposure on a faint star may not, and often does not, give exactly the same result for the color as a short exposure on a bright star; and if two stars, one near us and one very far away, look about equally bright to us, the remoter one must of course be really very much the brighter of the two. Now it may be that a very bright star showing a given kind of spectrum tends to be redder, or for that matter, bluer, than a faint one of the same spectrum; and before we can be sure that we have evidence of the absorption of light in space, we must prove that our results have not been vitiated by some such difference in the color of bright and faint stars.

Several previous attempts have met with trouble here; but a recent paper by Dr. Adams of the Mount Wilson Observatory seems to have surmounted the difficulty.

A number of pairs of stars were selected, the two stars of each pair being alike in spectrum and similar in apparent brightness, and the spectra of each pair were photographed side by side on the same plate and developed together, taking care that the stars were at the same apparent altitude in the sky at the time of the exposures, so that the absorbing action of our atmosphere should be the same for the two. One star of the pair is chosen, if possible, from the now extensive list of stars known from direct measures of parallax to be near us; the other is selected on account of its very small proper motion in the heavens, and is therefore presumably distant. If this star is really farther away than the other (which is probable but not certain in the individual case, but sure to hold true on the average), and violet light is absorbed more than blue light in passing through space, the spectrum of the remoter star should fall off in intensity toward the violet more rapidly than that of the nearer star. Such an effect is shown in fourteen out of the twenty pairs so far photographed, and in some cases the effect is very conspicuous. There is not a single example of the contrary effect. Since all disturbing factors have been carefully eliminated, it seems clear, even from this relatively small amount of evidence, that the distant stars actually appear redder than the nearer ones.

As we have already remarked, this might be because they are of greater real brightness, not because they are farther away. But a second series of plates is now being taken at Mount Wilson, in which the stars to be compared are similar in spectrum, but of very different real brightness, while at about the same distance from us. For such stars the effects of space-absorption would be the same, but the influence of differences in actual brightness would come in to their full value.

The few photographs so far taken for this purpose seem to show that the effect of differences in actual brightness is small, if perceptible at all. If this is confirmed by fuller study the existence of absorption of violet light, to a greater extent than blue, during its passage to us from the remoter stars, will apparently be satisfactorily proved

It will not improbably be possible to estimate how great the effect is for every hundred light-years of distance; and in this case it will become practicable to estimate the distances of very remote stars, now too great even to guess at, by finding out how much redder they are than near-by stars of the same spectral type.

The Heavens.

As our map shows, the most brilliant region of the sky is now well down in the west Taurus, Orion and Canis Major lie in a horizontal line, not far above the horizon, and above them are Auriga, Gemini, and Canis Minor. This small region of the sky contains five stars brighter than the first magnitude, and nine more between the first and second magnitudes. At the present time, Mars and Saturn are both within its borders and these too appear brighter than the first magnitude, making the western sky unusually well lighted.

The southern heavens, on the contrary, are very dull. Leo, high, near the zenith, is conspicuous, but the immense constellation Hydra, lower down, contains but a single oright star, and there is practically nothing below this.

In the southeast is the small, but conspicuous group Corvus, whose two uppermost stars point straight toward the still brighter star Spica, in Virgo. Due east, at a moderate altitude, is Arcturus, with his fainter companions in Boötes. Below on the left is the semicircle of Corona Boreales, and on the northeastern horizon Hercules is rising.

The Great Bear stretches northward from the zenith to the pole. Lower down, east of north, are Draco and Ursa Minor, while Cassiopeia and Cepheus are on the northern horizon.

(Concluded on page 187.)

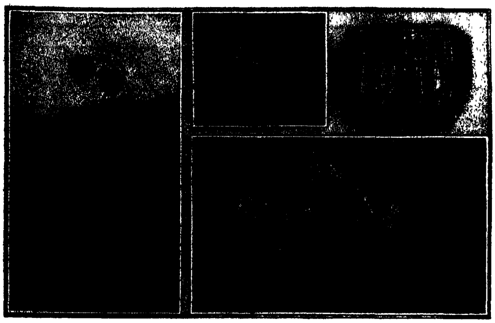
How's the Weather Up There?

By C. L. Edholm

BALLOONS sent up eighteen miles to report on weather conditions bring back the answer that it is rather chilly, 85 degrees below zero, to be accurate, which is some frost even for Medicine Hat.

As it happens, this report comes from a region nationally advertised for its mild climate, from Southern California, but the famous Pacific Coast climate is not claimed to extend indefinitely straight up.

Of course, no one was commissioned to ascend to an altitude of eighteen miles, or anything like that, merely to secure a weather report, but some very trustworthy messengers of aluminium and steel were sent up instead, delicate recording instruments inclosed in water-tight cases and carried aloft in wicker baskets by twin balloons. A series of twenty-three balloon weather soundings has just been completed at Avalon, Santa Catalina Island, off the California coast, by observers of the Weather Bureau, and the way they got results was unusual and exceedingly ingenious.



Recording weather conditions at high altitudes with sounding balloons.

The meteorograph, in its wicker basket, was suspended between two balloons of pure rubber, which were inflated with hydrogen gas and set adrift. On leaving the ground, these spheres had a diameter of 8 to 10 feet, but as they ascended, the air pressure decreased and the gas continued to expand until at an average altitude of fifteen miles the gas pressure from within became greater than any rubber could endure, and one of the twin balloons would burst. The weight of the instrument and basket was an easy load for two balloons, but it was too heavy for one alone to support aloft, so following the explosion of balloon number one, the second would slowly trail earthward, or seaward, and the meteorograph and the rubber sphere above it would float about on the waves until sighted by some passing vessel or fishing craft, or until the tides washed it ashore.

This seems as precarious as "casting bread upon the waters" in the hope of "return after many days," but as the Government allows a reward for the return of the instruments, the voyagers along the coast are alert for them. Before the entire twenty-three ascensions had been made, there were three recoveries, and it is probable that for months the announcement of further finds will be made. Those picked up during the recent tests were sent to Avalon, but the rest will be shipped as fast as received to Mount Weather, Va., to be opened and examined by the scientists stationed there.

When inflating the balloons, they were filled with enough gas to carry them as high as possible, and no variation in the amount of gas was provided that would cause the explosion of any one sphere before the other. This was left to chance, as the difference in the strength of the envelopes was sure to prevent simultaneous rupture.

The men conducting the experiments on Santa Catalina Island are all well known experts in their chosen work. Mr. B. J. Sherry has spent many years in research, and was placed in charge of the tests. His colleagues are Mr. W. R. Gregg, senior research observer at Mount Weather, and Mr. Paul Hathaway, the odolite expert, who traces the course of the balloons by means of his transit-like instrument. The photograph which shows the balloons in the air, just after leaving the Avalon golf links, as well as the detail views of the instruments, were taken by Dr. Ford A. Carpenter, weather forecaster at Los Angeles, who kept in close touch with the experiments.

When the aerial strays are safely gathered at Mount Weather, the work will be far from complete. The meteorograph records are traced by three needles upon an aluminium cylinder blackened with camphor smoke. Altitude, humidity and temperature are thus recorded, but very elaborate computation will be required on each record.

From the salt-encrusted instruments recovered and sent to Avalon, it was found that the air grew steadily cooler up to an altitude of about eight miles. There the extreme of 85 degrees below zero was recorded, but though some of the balloons went much higher, the temperature did not show more intense cold; on the contrary, it was just a trifle less chilly. This indicates a belt of even temperature of unknown thickness above that part of the earth, extending above the so-called "storm zone," which is within the eight-mile limit.

Above this zone the air currents of Southern California seem to have a steady trend from the southwest to the northeast, while below this the currents are variable; generally from the west

It is hoped that permanent stations in the West and Northwest may be established for balloon soundings at great altitudes, as a prolonged observation of the results would undoubtedly throw light on many a problem that has puzzled the weather man, and enable the forecasters to predict with far greater accuracy the approach of storms and the other phenomena that are of such direct and practical importance to the average man.

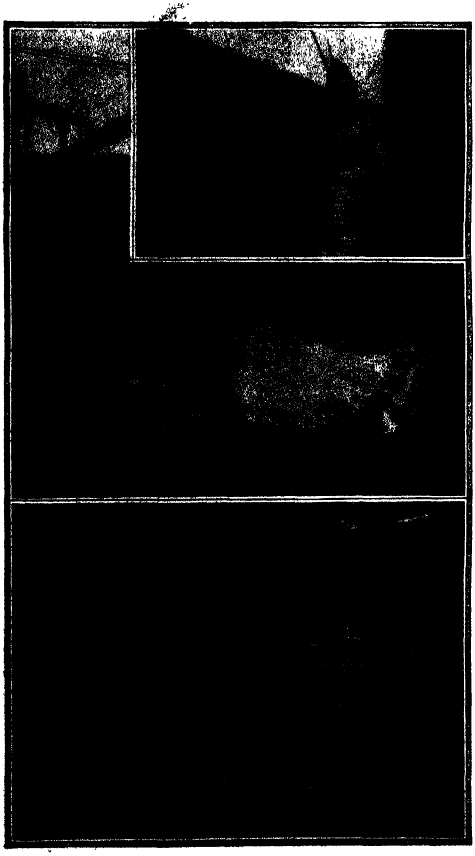
A Novel Hull-cleaning Apparatus

AN Australian inventor has concentrated his energies upon the perfection of an apparatus and method which, while effectively cleaning a vessel's hull, at the same time enables the operation to be achieved quickly, cheaply, and without the necessity for dry-docking. He realized that the cleaning of the hull could be carried out while the vessel was discharging and reloading and not at all delaying her

The cleaner comprises a flat-bottomed barge thirty feet in length by twelve foot beam, which draws from two and one half to three feet of water. It is fitted with a special winch, submersible brushing gear, and the necessary electric generating plant. A crab winch fore and aft suffices for manipulating the mooring ropes There is also a propelling motor for driving the barge, which is thus able to move under its own power at about five knots an hour

The cleaning gear consists of a brass and gun metal frame in which is mounted the brush, electric motors, and the propeller, the last constituting an outstanding feature of the invention The brush is longitudinally mounted upon the front side of the frame. It is five feet in length by twelve inches in diameter, and is fitted with two and one half inch fiber bristles Behind the brush is a three-bladed phosphor-bronze propeller Between the brush and its propeller an electric motor is fixed for driving both the brush and its propeller. The motor is of a special submersible type and receives current through a three-core rubber-sheathed cable The brush is driven by chain gearing from an intermediate shaft, which itself is driven through worm gearing by the motor. The latter also drives the propeller.

In operation the barge takes up a position alongside the vessel to be cleaned, and is made fast fore and aft. The brushing gear is lifted overboard by means of the winch and derrick, and is lowered into the water The brushing motor then is started. The action of the brush propeller, combined with the manner in which the gear is slung overboard, forces the frame gearing and revolving brush hard against the vessel's hull, and the propeller keeps it well up to its work While running, the gear is gradually lowered in a vertical direction, still pressing against the hull, to such a depth as the steamship's draft may require The gear is then raised to the surface, the brush still rotating, the barge is moved forward a distance of four feet, and the operation repeated. It will thus be seen that the hull is cleaned in vertical strips, and although the latter are five feet wide—the length of the brush—by moving the barge forward only four feet at a time, an ample margin is provided to insure complete overlapping of adjacent cleaned strips



A machine that scrubs barnacles from ships' bottoms.

The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles.

The Motor Truck in Snowbound Streets

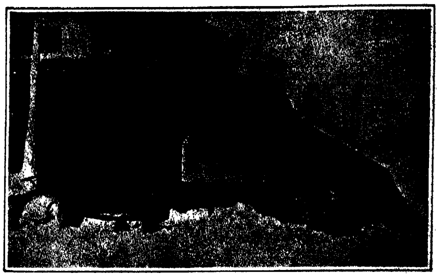
THE seventh annual automobile number of the SCIENTIFIC AMERICAN, published in January, 1905, had on its cover the picture of an automobile in a snowstorm. This was so unusual a scene as to create a sensation. Up to that time the motor car had been looked upon as a pleasant weather vehicle, to be stored in the garage at the first fall of snow. Little did we think then that within a few years it would be our mainstay in winter storms, not merely for passenger service, but for the transport of merchandise; that when the ordinary wagon could barely be kept moving with the aid of two and four extra horses, large motor trucks bearing many times the load of coal or milk or other indispensable commodities would pursue their powerful course despite the obstructing snow.

We in New York had almost forgotten that the motor truck was so efficient until we were suddenly overwhelmed the other day by a heavy snowstorm—the first of any consequence in over a year. At the first opportunity we sent our photographer out to record some of the difficulties of vehicular traffic, and to show how motor trucks were getting on under such adverse conditions. The manner in which motor vehicles plowed along despite the heavy handicap was very gratifying To be sure, there were many sections which even they could not traverse, but by comparison with the work of the horse that of the motor was remarkable.

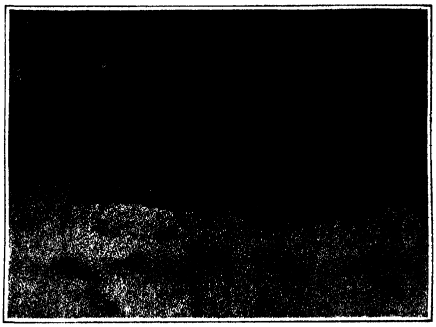
The poor horse is not provided with a reduction gear which will enable him to use his powers to better advantage. Unfortunately, he is a direct connected motor and there is no way of easing up the work without the use of tackle, which obviously is impracticable in congested streets.

Although a motor may be powerful enough to turn the driving wheels, under any conditions, this does not necessarily mean progress, for the wheels may slip, and therein lies a weak spot in driving motor vehicles through snow. Without tire chains or their equivalent progress is almost impossible. In some situations even tire chains do not furnish sufficient grip.

Another weakness is to be found in the differential which permits one wheel to remain stationary while all the power of the engine is expended in idly spinning the other. Formerly electric vehicles used two motors, one for each driving wheel; but the advantages of a single motor have led to its almost universal adoption despite the necessity of employing a differential gear; and so now the majority of electric trucks are in the same class with the gasoline truck as regards this particular weakness



Faithfully at work in a blizzard "tie-up."



Breaking a path through deep snow.

Motor delivery wagons proved invaluable to the department store.

The photographs shown on the accompanying page were, with one exception, taken on the streets of New York and Brooklyn. The one exception is that of a five-ton coal truck which did remarkable work in Cleveland, Ohio, during the blizzard of last November. It happened that this truck had been promised to a coal company in Cleveland for a demonstration during the worst days of the storm, and although vehicular traffic throughout the city was practically at a standstill, this truck started out Monday morning with an inexperienced driver and worked steadily without stop until 8 A. M. Tuesday. Two hours later the truck started out again and worked until 3 A. M. Wednesday, and then beginning again at 7 A. M. Wednesday it worked until the afternoon, when it started hauling groceries. During all the working hours the engine was kept running continuously and little time was spent in loading and unloading. While the truck was in service the coal company tried to use its teams as well, but found it impossible to get around with four and six horses to a wagon. Altogether during the three days of the storm it ran about five thousand miles and used up over sixty feet of tire chain, the action of the snow causing the links to twist and break off. A better record for a motor vehicle could hardly be desired.

Steel vs. Wood for Motor Truck Wheels

By Elmer J. Lamb

A RIGID and exacting series of tests has just been completed in the school of mechanical engineering at Purdue University to show the relative efficiency of steel and wood as material for motor truck spokes. In the investigation wooden wheels constructed according to the specifications of the Society of Automobile Engineers and steel wheels of standard dimensions, but of steel stampings, were used. The tests were conducted under the direct supervision of Professors L. V. Ludy and H. H. Schofield. They included not only tests to which a wheel would be subjected under actual road conditions, but also such as would show the ultimate strength in every detail. The wheels were subjected to four tests, and in each the steel wheel built for a load of only a ton and a half proved superior to the wooden wheel built according to 2-ton truck specifications. The steel wheel was built entirely of steel with the exception of the rim, which was built of wood, so that it might be available for any kind of a tire. The rim and the hub were connected by a pressed steel web fastened together with rivets.

The tests brought out clearly the present difficulty experienced by most manufacturers in obtaining a grade of lumber sufficiently uniform for the manufacture of automobile wheels. The present scarcity of good material makes it possible that

Pursuing its powerful course despite the storm.

The snow did not stop the delivery of pianos.

[illegible] In the case of the wooden wheels failure was always apparent in one place, thus showing slightly defective material, although as a whole they fulfilled the specifications. The steel wheels when tested beyond their capacity gave away more uniformly.

The first experiment corresponded to the twisting force or torsion of the hub on a wheel mounted upon the driving axle of a truck traveling under a load. The load was applied to the rim of the wheel and the rim held stationary, while a force was applied to the hub so as to twist it. The force was applied in the manner that the drive of the motor would be applied under actual road conditions.

The second test consisted of holding the wheel stationary on the axle and applying a load to the rim on one side, corresponding to the force exerted on the wheel of a truck, skidding and striking a curb or other obstruction.

In the third test a wheel was placed in a vertical position on its rim in a static testing machine and the load applied directly across the diameter, the load being increased to determine the strength of the wheel. Finally, the wheel was supported by the rim on two sides, lying horizontal, and the load was applied to the hub. According to the university authorities there is no record at the present time of any wheel's being submitted to this test in the past.

Minnesota Road Patrol System

MINNESOTA'S designation of 11,000 miles of arterial roads as the State road system has already done much to advance the land values and place the "North Star State" among the first rank as regards road improvement. In 1914 Minnesota will spend $2,500,000 for roads and bridges, and will inaugurate a system of road patrols for the maintenance of the State roads. Nearly 1,500 patrolmen will be assigned to five and eight-mile sections of the State highways, and will be held responsible at all times for the condition of the roads. The plan was originated and adopted at the request of State Highway Engineer G. W. Cooley. Twenty per cent of the one mill State road tax and a similar amount of the county appropriations for road work must be used for maintenance under the law passed a year ago. This makes available $500,000 for the new patrol system.

Motor Truck Notes and Queries

D. L. C. writes: "The 30 horse-power motor of my two-ton truck seems to lose power on a hill and to pound and knock, even though the spark is well retarded. Another business man in town who operates the same kind of a truck tells me that there is probably an accumulation of carbon in the cylinders, and that this should be removed if I would obtain satisfactory results from the motor. It is quite probable that this should be done, but I cannot spare the truck for the several weeks that would be required to overhaul the engine. Is there any short-cut by which I can overcome this difficulty, and how may I best avoid such trouble in the future?"

A. From the symptoms that you have given, it seems probable that your friend's diagnosis is correct, but it is hardly necessary to dismount the motor entirely for the removal of the offending carbon. By a new process, it is only necessary to remove the valve caps and introduce a certain form of blowpipe into the combustion chamber. This blowpipe is connected with an oxygen tank, and when united with the carbon in the cylinder, forms an ignitable mixture that will burn the cylinder and piston heads absolutely clean of the carbon deposit. The flame is automatically extinguished as soon as the carbon has been burned, and therefore the heat [illegible] the interior of [illegible]. It is advisable, however, that the piston should be at the top of its compression stroke in the cylinder before the mixture is ignited, for the heat would be liable to scorch the smooth surface of the cylinder walls over which the piston passes. The operation requires but an hour or so for the removal of carbon from all four cylinders, and the engine is cleaned more thoroughly than would be the case were the surfaces scraped. One of the most satisfactory methods of avoiding the accumulation of carbon in the cylinders is to pour a couple of ounces of alcohol through each priming cup or spark plug opening when the motor has finished its work for the day, but is still hot. This will serve to loosen what carbon may be collected, and it will be blown out with the exhaust when the motor is started the next morning. It is advisable to do this about once a week, although the use of the correct amount and proper quality of lubricating oil is an important consideration.

P. N. E. writes: "A few years ago several motor trucks of leading makes were designed with a differential lock. What was the purpose of this, and is it considered an advantage?"

A. The differential lock was designed to give the effect of a solid rear axle so that each wheel would revolve at the same speed, regardless of tractive conditions. It was designed especially for trucks that were to be used over country roads where there was a liability that one wheel would strike a soft and slippery place. In this case, the differential would transmit the motion intended for the one wheel to the other that was free to revolve, and this would spin at high speed without moving the truck. A means of locking the differential caused the power to be transmitted equally to each rear wheel, and therefore the one that rested on the good tractive surface would move the truck out of the mudhole. Of course the use of chains, ropes, or other similar devices would prevent this slipping and would serve the same purpose as locking the differential. It is claimed by some engineers that the differential on a motor car is a prolific source of skidding, but its use is necessary if it is desired to save tire wear.

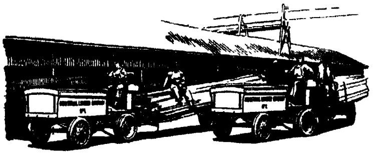
L. K. J. asks: "What is the attitude on the part of the leading truck manufacturers toward free service and maintenance guarantees?"

A. Many motor truck manufacturers are awakening to the injustice that is being done themselves, as well as the industry as a whole, through the abuse of service guarantees. The manufacturers cannot be expected to be held responsible for poor service obtained from a truck because of flagrant abuse on the part of the owner or driver. The most satisfactory system seems to be that in which the truck dealer undertakes to store and care for his client's car for a stipulated sum per month, and to guarantee service during certain hours of every working day of the year. For this guarantee, the dealer charges a sum sufficient to show a reasonable profit on the storage, gasoline, oil, and necessary overhauling, while repairs that are caused by defective parts are cared for by the factory guarantee. Such a service is maintained in many of the large cities where certain trucks are sold, and this system has proved advantageous to dealer as well as truck owner. If the service contract includes keeping the truck in repair, the dealer generally stipulates that he shall furnish the driver, and that the owner himself shall not be allowed to make any adjustments. Furthermore, the truck must be stored in the dealer's garage so that it will be constantly under his care and he may know that it is operated properly. Knowing the truck as he does, the dealer is then able to assume responsibility for its regular over-capacity whenever the first vehicle is out of commission. Such a system naturally saves bickering and hard feeling between truck manufacturer or agent and owner, and this is a healthy sign pointing toward the elimination of the much-abused free truck service.

The G. V. Electric Tractor
Gives Startling Results

IN ALL our 13 years' experience involving many types of Electric commercial vehicles, we have never produced a more instantaneously successful storage battery vehicle than the G. V Electric Tractor

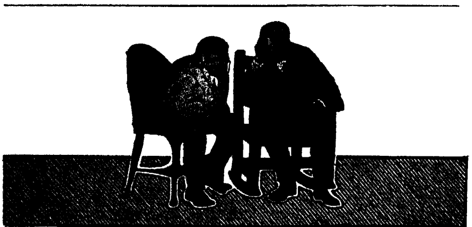
THREE of these machines built for a big lumber company in Louisiana displaced 20 mules, operating over 5 miles of tramways. The labor charges of the old method aggregated $10,500 per year; of the new method, $3,600. The total saving effected reaches the sum of $13,243 per year! This is more than the initial tractor investment.



THE tractors shown have a 2-ton rating, a speed of 10 or more miles per hour, and a normal mileage of 35 per charge. We are building a 3½-ton tractor for the N. Y. Street Cleaning Department. (Repeat order)

THESE new G. V. Tractors cannot perform miracles, but where they can be used to advantage the saving is wonderful. If you have a towing problem, write at once for Bulletin No. 101. You'll find it interesting, anyway

GENERAL VEHICLE COMPANY, Inc.
General Office and Factory:
Long Island City, N. Y.
New York Chicago Boston Philadelphia



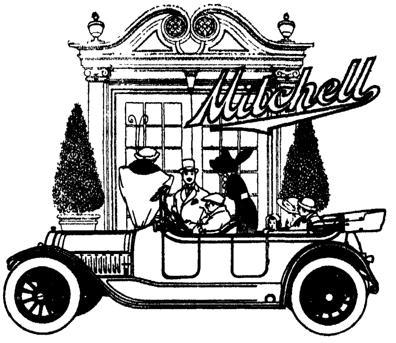
Steinmetz Says:

"I believe that the Electric will be the car of the future on account of its simplicity of operation and reliability. It is rare that it gets out of order. When it does so it is an accident—not as with the gasoline car, an incident. The man of moderate means cannot afford a horse and buggy because of the attention required. He will be able to afford an Electric Vehicle to take him to business because it requires no attention—if equipped with an *Edison* Battery. It often has to stand idle for several days and this is not good for a lead battery. I have tried to invent a lead battery that would not spoil, but gave it up."

O.K. Chas. P. Steinmetz

From an Approved Report of Some Extemporaneous Remarks of Dr. Chas. P. Steinmetz at a Recent Meeting of Engineers.

EDISON STORAGE BATTERY COMPANY
132 Lakeside Avenue, Orange, N. J.
The Edison Nickel-Iron-Alkaline Storage Battery is the ONLY One. Contains no Lead nor Acid



Mitchell Big Six
at $2,350.00

The Mitchell Big Six is a classy, powerful, speedy, *aristocratic looking car* seating seven passengers and propelled by a long-stroke, sweet-running silent motor.

It has sixty horse-power, 144 inch wheel-base, 37-inch tires and a magnificent spring suspension, proving to you that nothing has been left undone to insure *easy riding and bodily comfort*

In addition to the above the car is upholstered with soft ten-inch cushions and is finished in a manner that will please you no matter how exacting your taste may be

It offers more *car*, more *quality*, more *comfort*, more *power* and *longer life* than any car that is sold in America today at $3,000. It is beyond question *the high-class, low-cost car* and you will experience a definite pride in its possession.

Equipment of the Big Six included in the list price—electric self-starter and generator—electric light plant—mohair top and dust cover—quick action rain vision and wind shield—speedometer—extra removable rim—double extra tire carriers—license plate bracket—Bair bow holders—electric exploring lamp—electric horn—pump-jack and set of tools

A Triumphant Struggle With a Beetle

(Concluded from page 180.)

proportion of infections was very small. If 100 sound larvæ were imprisoned in a salmon case with say 20 infected ones and fed on rotting materials, no more than six or eight of the sound larvæ would, during these early days of experiment, be attacked by the fungus. From his own experiences with these beetles, and with this fungus, Dr. Doane did not see much relief in that direction, and so reported. However, Dr. Friederichs continued his patient labors and eventually he bred new habits into the fungus, created a new appetite for the living larvæ of the beetle, and at last produced such a virulent fungus, that when five or six infected beetles are confined with one hundred sound ones, 98 per cent or more will soon find themselves in trouble.

It has now become the custom in German Samoa to carry infected rubbish and beetle larvæ to the outdoor "Tumus," and deposit it in them, and as one of these is placed on every acre of cocoanut lands, and as the mother beetles are very fond of these artificial nests, nearly all of the eggs deposited come to nothing at all.

The strength and efficiency of this fungus has now so greatly increased that many of the mother beetles coming to oviposit are themselves attacked and they fly away with enough of the infection to poison the galleries in the cocoanut trees and spread the contagion among their neighbors.

The Samoans who under the law gather beetles and larvæ every Monday morning are now bringing in quantities of fungus-fed beetles, and the plague is very much abating.

Here in the islands we regard this achievement as a remarkable one; and as this means of combating the greatest enemy the cocoanut tree has, ought to be known in all tropical countries, we send it to the SCIENTIFIC AMERICAN, which circulates everywhere, and whose word is taken as emphatic and dependable.

Prolonging the Naval Stores Industry

(Concluded from page 173)

trees or in cutting the boxes preparatory for the next season's flow. As a result of this work a certain amount of crude turpentine is collected during the winter, but it is almost entirely from ducts already in the wood and not from secondary ones. The flow of this resin does not continue very long, for the wound becomes clogged, presumably from oxidation and crystallization of the resin, and the flow ceases

The secondary resin ducts formed above the wound are filled with resin which has no opportunity to escape until a thin chip is cut off. When this is done the flow is much more vigorous than from the original wound. In about a week, however, clogging up occurs again and another chip must be removed As this wound extends slowly up the tree new or secondary ducts keep pace with it If too large a chip is cut the productive secondary ducts are cut off and the run materially lessened.

Failure to understand the physiology of resin formation and to adjust the methods of turpentine orcharding to it has resulted in untold losses and a very serious depletion of a valuable resource. It is also responsible for one of the chief criticisms against the cup and gutter system. It is a common experience that, although the total yield from the first year of the operation is greater than under the box system, nevertheless an unusually large number of weekly chippings has been found necessary to secure the first dipping from cups—six to seven chippings as compared to four under the box system.

In the light of the above explanation of the formation of secondary resin ducts this shortcoming is readily explained and avoided. Under the box system the boxes are cut during the winter and the trees are "cornered," that is with the upper edge of the face ready for chipping. The new ducts form, the first chip opens them up the full length of the cut and a good run is at once secured. In placing cups, however, the common practice has been

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN

AGENTS WANTED

AGENCIES WANTED for Australia or N. S. Wales. Articles of merit and patents. Mechanical preferred References and instructions cabled. M. A. Stewart, Box 1915, G. P O , Sydney, Australia.

FOR SALE

BRAZILIAN GOLD, diamond, iron, lead and limestone, etc., mines, railway concessions, pasture and timber lands, etc. for sale. Apply to Hilario Castanho, Business Agent, Rua Paulista No. 39, S. Paulo City, Brazil, South America.

MISCELLANEOUS

HOW TO RUN A LATHE. A 50-cent book for 10 cents, postpaid. Stamps accepted. By a practical machinist and a mechanical engineer. South Bend Lathe Co., South Bend, Ind

INDIAN BASKETS, best on earth, beads, wampum, pipes, points, spears, all kinds of Indian relics. For further particulars apply to F. Gilham, Highland Springs, Cal.

INVENTIONS PERFECTED—Ideas developed. Expert in the development of patents. Legal and Technical *advice free*. R. Sheimo-Jacobsen, Consulting Engineer, Dept. B, 452 Peoples Gas Bldg., Chicago Ill.

GREAT OPENING FOR YOUNG ELECTRICIAN. A strong company ready to begin small hydro-electro development to light four towns in prosperous part of Wisconsin needs a superintendent immediately. Must be a hustler of good habits with practical experience and some money to invest. Liberal contract with profit-sharing to right man. Ample references given and required. Address, Superintendent, Box 773, N. Y.

INQUIRIES

Inquiry No 9350 Wanted the name and address of the manufacturer of a printing press for the printing of tapes for clothing The machine should preferably be worked by hand.

Inquiry No. 9351. Wanted to make some article out of wood which could be made from 2 inch ash, by party having 75,000 or more *feet of waste* per year which is now used for fuel.

Inquiry No. 9352. Wanted the name and address of a person who is in a position to get the state or county agency for articles of merit that can be sold to business houses or others at $3.00 or over. No kitchen utensils desired.

Inquiry No. 9353. Wanted the name and address of a manufacturer who can make flexible oil cans.

Inquiry No. 9354. Wanted the name and address of a manufacturer of a machine which will stitch silk around small metal rings

Inquiry No. 9355. Wanted the name and address of the maker of triplex glass.

Inquiry No 9356. Wanted the name and address of a manufacturer who can build an *automobile wheel*, also a *cigar vending machine*. Concerns in the middle West preferred.

Inquiry No. 9357 Wanted the name and address of a manufacturer of a machine for scalloped paper favors and cups.

Inquiry No. 9358.—Wanted the name and address of maker of a machine to cut all granulate leather.

Inquiry No. 9359. Wanted the name and address of a firm that makes razor blades for all makes of safety razors

Inquiry No. 9360. Wanted the name and address of parties making pipe fittings such as ferrules, stems and bowls such as could be used in the making up of calabash pipes for smoking.

Two Cents a Week Pays Wash Bill!

This Washer eliminates *labor* and practically saves all *cost*. Does a big family washing *for 2 cents a week*—yes, and the *wringing*, too! It's one of the greatest marvels the world has ever known. Runs by electricity or water power. Washes a tubful *spotlessly clean* in two to six minutes! Wrings out the clothes to perfection as fast as you feed them—prove it at our expense.

Make it one long vacation—a summer of boating pleasures such as have hitherto been enjoyed only by those so fortunate as to own launches. Be one of those fortunates yourself this summer. Skim about wherever you wish over river and lake, to the hunting or fishing grounds—the camp or summer home. You can do it at a trifling expense. All you need is a common row boat and a

Caille Portable Boat Motor

If you haven't a row boat, get a motor anyway and attach it to any rented boat. It only weighs 55 pounds and can be easily carried in our handy carrying bag to any renter's landing. It attaches to any row boat by simply turning two thumb screws. Can be easily adjusted to any angle or depth of stern. Steers by a rudder—like a launch. Develops 2 horsepower. Can be run in salt or fresh water.

Send for Catalog

Get ready for that summer of fun now. Write today. Reliable hardware and sporting goods dealers wanted to handle this motor.

For Larger Launches we build a complete line of motors from 2 to 30 H.P. If interested, ask for our Marine Motor Blue Book.

to make with the broad ax two flat faces, meeting at the center, on which the cuts for insertion of the gutters are made. The upper portions of these faces have oval outlines instead of straight as in the preceding case. The resin ducts formed follow the curved upper edges of the faces. The first chipping is made from each side to the center, and the result is that instead of the new ducts being opened up along the entire cut, only those near the middle of the face are cut. Naturally the flow at first is considerably less than where the trees are "cornered."

The solution of the difficulty presents itself immediately the cause is understood. During the winter months, when the gutters are placed upon the trees, the chipper should make a regular chipping the full width of the face. Secondary resin ducts will form along the entire length of this cut and the first application of the hack in the spring will start them all to flowing at once. Actual tests have demonstrated the correctness of the theory and resulted in a gain of one extra dipping or about thirty barrels of crude turpentine per crop of 10,000 cups. The saving to the entire industry is enormous.

French turpentine is considered superior to American. It is obtained from maritime pine (*Pinus maritima*), which produces a resin yielding 25 per cent turpentine as compared to 17 per cent for long leaf pine. The tree has the ability to grow rapidly on poor sandy soils. The United States Forest Service is now experimenting with it in Florida, and the prospects are so far very promising. Maritime pine grows more rapidly than loblolly and produces more resin than long leaf. It attains size large enough to cup in thirty years as compared to one hundred years for long leaf. There are large areas of cheap land in the South which are well adapted to its growth in case the experimental plantations fulfill their present promise of success.

The Heavens in March

(Concluded from page 182.)

The Planets.

Mercury is evening star until the 10th, when he passes through inferior conjunction and becomes a morning star; but he can only be well seen at the very end of the month, when he rises an hour before the Sun.

Venus is evening star, and is coming into sight again, so that by the end of March she sets an hour later than the Sun, and is easily seen.

Mars is in Gemini, long past opposition, but still about as bright as Procyon. During the month he moves eastward about 10 degrees, and his motion can easily be followed with the naked eye, even from night to night, especially on about the 8th, when he passes about 1 degree north of the third magnitude star ε Geminorum.

Jupiter is a morning star in Capricornus, rising about 4:30 A. M. in the middle of the month. Saturn is in quadrature with the Sun on the 2nd, and after this counts as an evening star, though he remains visible till about 1:20 A. M. at the beginning of the month, and 11:30 P. M. at its close.

Uranus is a morning star in Capricornus. At 4 A. M. on the morning of the 4th he is in conjunction with Jupiter, being south of the brighter planet, at a distance of only nine minutes of arc. The two planets will be separable only with the aid of a field-glass, and Uranus will appear about as near Jupiter as his own satellites, but in quite a different direction. Unfortunately, this interesting conjunction can only be observed under rather unfavorable conditions, at about 5 A. M.

Neptune is in Gemini, and crosses the meridian a little after 8 P. M. in the middle of the month.

The Moon.

First quarter occurs at midnight on the 4th, full Moon at 11 P. M. on the 11th, last quarter at 8 P. M. on the 18th, and new Moon at 1 P. M. on the 26th. The Moon is nearest us on the 12th, and remotest on the 27th. She is in conjunction with Saturn on the 4th, Mars on the 6th (pretty closely), Neptune on the 6th, Uranus on

The Real *Science* of Motor Truck Tire Equipment

Experienced truck operators no longer bargain on the basis only of a certain size, a certain mileage adjustment, at a certain price.

The Firestone practice of closely classifying all delivery, hauling and transportation requirements has put tire equipment on a **scientific** basis—as much better as it is different. **Your class** or classes of tire needs, for maximum truck efficiency at minimum cost, are among those analyzed by the Firestone experts.

Firestone

Truck Tires and Quick-Removable Rims

There is a Firestone tire to meet each and every need, made to specifications with uncompromising accuracy. That is the tire which will cost you least to use, though it may cost most to build. That is the tire which the Firestone man will recommend for your requirements.

Firestone Quick Removable Rims are an insurance against delivery delays Tire changes are easily and quickly made by the truck driver himself

Firestone Salesmen sell Service. They sell most protection to truck mechanism, most miles without wheel trouble or delays, most miles per gallon of fuel—**most mileage, most service, per dollar.**

Write for truck equipment catalogue. Let that convince you of Firestone preparedness Then call in a Firestone man for consultation, no matter how small the order involved.

How Far Back Does Your Memory Go?

Have you ever given your memory a real test?

Take some object that you are accustomed to seeing every day—the electric light for instance.

When did you *first* see an incandescent electric lamp?

Stop and think a minute! It's almost impossible to recall your first experience with such familiar things, isn't it?

And just think, away back in 1879, when Edison exhibited his *first* incandescent lamp—Richmond Straight Cut was already considered the "Henry Clay" of cigarettes. In the changing years that have followed, it has never lost its place. It is still the best of all Virginia cigarettes.

True, our memories may be fickle with the crowding, commonplace incidents of busy days, but which of us does not remember quality?

20 for 15c Liggett & Myers Tobacco Co.

Friends for forty-two years

the 21st, Jupiter on the 22nd, Mercury on the 24th, and Venus on the 27th.

At 6:03 A M. on the 21st, the Sun crosses the celestial equator and "Spring begins," technically speaking; and on the night of the 11th there is a large partial eclipse of the Moon, which is well observable throughout the United States.

The Moon first reaches the penumbra of the Earth's shadow at 8:41 P. M. by Eastern standard time. The umbra, or dark shadow, is not reached till 9:42. From this time on the eclipsed area increases until, at 11 18 P. M., eleven twelfths of the Moon's diameter is immersed in the shadow. Then the eclipse diminishes, and the last contact with the shadow occurs at 12:44 A. M., though the Moon does not clear the penumbra till 1:45.

This eclipse is so nearly total, and occurs at such a convenient hour of the evening, that it should be watched by great numbers of amateur observers.

Further observations of Delavan's comet, of which we spoke last month, and the orbit calculated from them by Van Biesbroeck, show that its perihelion distance is actually about ten per cent greater than that of the Earth, the inclination of the orbit about 68 degrees, the motion direct, and the perihelion passage not until October 26th, 1914. The comet is still very unusually remote from both Earth and Sun, its distance from the latter being more than four astronomical units at the time of discovery. It must be a very big comet to be visible at all at this great distance. When near perihelion next October it will be high in the northern sky, probably visible to the naked eye, and perhaps fairly conspicuous, though its perihelion distance is rather large for the formation of an extensive tail At present it is of the magnitude 10.8, and its position is as follows:

	R A	Declination.
March 1 . . .	2h. 42m. 22s.	3° 40′ N.
March 13	2h. 47m. 21s	5° 54′ N
March 25 . . .	2h. 54m. 12s.	8° 9′ N.

It is getting rather near the Sun, and is observable only in the early evening.

Princeton University Observatory.

The New Wright Aeroplane Control

A NEW form of aeroplane control has been devised by Orville Wright, and is thus described by him:

"The usual lever system has been replaced by an automobile type of steering wheel in combination with a handle, which makes the control not only stronger and simpler, but makes it much more effective. Formerly the elevator was controlled by a forward and backward movement of a lever in the left hand, while the warping and rudder were controlled by the forward and backward movement of a lever in the right hand, the rudder being offset for a turn by turning the handle of this right hand lever. This control, which has been used ever since 1908, was very effective for exhibition flying, for which it was particularly designed, and has proved a very precise one when once mastered. But for long distance flights many aviators found this control tiresome, and in the new and safer machine it is necessary to modify it into the new form.

"The steering wheel is of automobile type and the control is perfectly instinctive, the wheel being pushed forward and backward to control the elevation of the machine and turned from side to side to balance it laterally. In turning the wheel from side to side the rudder handle is turned with the wheel, thus giving a perfect lateral balance, and in turns it is only necessary to offset the rudder handle to one side or the other, still controlling the lateral position of the machine by turning wheel and handle together sideways.

"This type of control was adopted after very careful study had been made of all existing systems, and combines many features that have become standard in Europe. The control for lateral balance by the steering wheel is a standard requirement in the German army and is used on the German Wright aeroplanes

"The novel feature of the control is the simple manner in which the rudder control is combined with the warping."

Jeffery

A Million Dollars In a Week

A thousand cars in seven days—a million dollars' worth of Jeffery Fours and Sixes sold in a week—that is the record established by the Jeffery organization at the Chicago show.

One hundred and thirty-eight cars were sold for immediate delivery. Dealers' orders were taken for one thousand and seventeen for delivery before April first.

Seven thousand dealers' orders have been taken to date. This number exceeds the possible production of the big Jeffery works for five months to come. It means that in March, April, May and June, Jeffery cars will be hard to get.

The public now knows that the Jeffery Four leads the medium priced field. It is now simply a question of factory production and deliveries.

Fifteen hundred and thirty-nine people registered for demonstrations during the Chicago Show. Manufacturers of other cars, salesmen interested in other lines and dealers selling all cars came to see the Jeffery—all conceded the Jeffery Four at $1550 to be without competition.

A buyer stepped into the exhibit of a five thousand dollar car near us. He said, "What do you think of this Jeffery over here?" The salesman replied, "I think so well of it that I told a friend of mine—who cannot pay our price—to go and buy a Jeffery."

Thirty cars a day are being produced in the Jeffery works. Think what it means to build that number of cars in the Jeffery way.

Fifty-six Jeffery Fours and Sixes were shipped by the factory on a day when a blizzard was raging through the country. The Jeffery pay roll today is the largest in the history of the company. The shipments for January exceeded by one hundred per cent those of January one year ago. February beat the same month last year by two hundred per cent.

A great period of prosperity is opening up in this country and the big Jeffery organization, with the new Jeffery Four and Six, is on the wave.

There are reasons for this prosperity. Here they are:

The Jeffery Four is the first light weight, high grade car, equipped with a modern European type of high speed bloc-type motor, to sell in this country for less than $2500.

Take it from the tip of the radiator to the tail lamp and there is quality in every detail. Bosch Duplex system, Rayfield carburetor, electric starting and lighting system, four speed transmission, imported annular ball bearings, Spicer universals, full floating type rear axle with imported annular ball bearings, Rothschild body, and quick getaway—from nothing to forty miles in twenty seconds.

In 1916 the Jeffery type of car will be more common. The great demand for light weight and economy is forcing other manufacturers to imitate us. The day of the big, bulky car is gone and the Jeffery car is the car of the hour because—

Come "Evinrude" With Us

Do you know what "Evinruding" is? It is not a **new** sport because too many thousands are "Evinruding" to call it new. Dictionaries should describe it as making a motor-boat of any rowboat in less than one minute—of realizing all the pleasures of row-boating with any rowboat or canoe. The

Is Vibrationless, quiet and smooth running.

TRADE MARK
EVINRUDE
DETACHABLE
ROW-BOAT-MOTOR

Is powerful enough to tow several other boats.

IT WEIGHS ABOUT 50 POUNDS AND CARRIES LIKE A SUIT CASE

You Don't Need to Own a Boat

if you have an "Evinrude" because the "Evinrude" will attach to any boat whether rented or owned and its simplicity of operation enables women and children to enjoy the pleasures of "Evinruding" everywhere.

In designing our 1914 models we have made them the most modern achievements in gasoline motor construction. To add to their well known, great efficiency we have installed another exclusive Evinrude feature, the

Built-In Reversible Magneto

which eliminates the carrying of 15 or 20 lbs. of batteries necessary with similar motors. This magneto starts the motor with one-twelfth turn of the fly-wheel in either direction; is not affected by water or dampness.

The motor drives the average rowboat 8 miles an hour or may be slowed down for trolling. Speed with a canoe 12 miles an hour. The "Evinrude" has been adopted by twelve governments and is used universally.

Call at your Hardware or Sporting Goods Dealer to see the "Evinrude" or write for large illustrated catalog sent free.

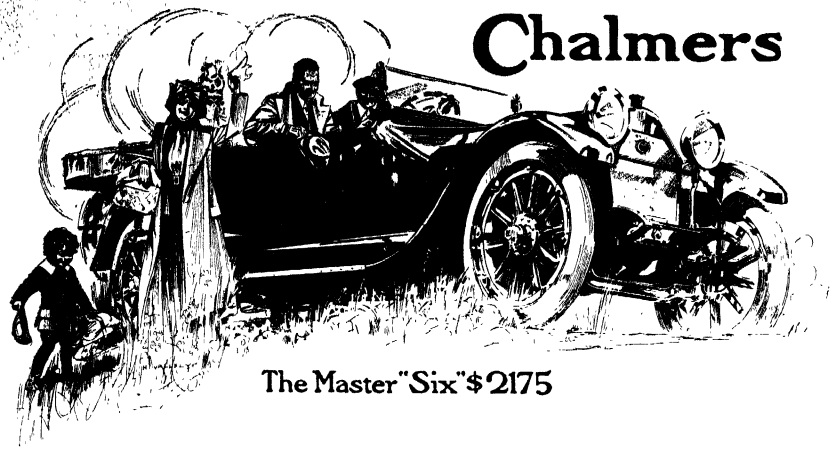
Chalmers



The Master "Six" $2175

Motor Folks call me the Master Six.

I have earned the title. I have set a new record for sixes. In one month alone men paid over $2,000,000 for me. They had all the sixes of the world to choose from. They chose me.

But first they made me prove myself. They put me to tests equal to a season's service. Only by living up to every claim did I win them.

Because I told my story in deeds rather than words—they were convinced, for they couldn't deny what their eyes saw—what their senses perceived.

Let me tell you in deeds the story of my master motor. It will win you as it won them.

The Turning of the Tide

Swiftly and surely the tide has turned to the Sixes. Motorists no longer are content with a power that lets go and grabs again at every other revolution. They now insist upon that quiet, steady pull, that luxurious smoothness that can come only from six cylinders.

Until the Master Six appeared last year, buyers had thought of all Sixes as heavy cars, extravagant of fuel and tires; costly to buy and expensive to keep. But the Master Six opened their eyes.

Here was a car of six cylinders at a moderate price, and even lighter than many 'fours' of equal power. Here was a motor so silent and smooth running that friction and wear might be forgotten. A car which costs little to buy and little to keep.

Power Lithe as a Panther

Its master motor has six cylinders of long stroke and small bore. So it fairly floats up the hills on high gear. It can reach twenty-five miles an hour in ten seconds from a standstill. It can creep like a snail through the crowd and then be off like a greyhound at the touch of the throttle.

This ability to run fast or slow on direct drive, to vary the speed at will without constantly shifting gears, puts the Master Six head and shoulders above its rivals. It gives a flexibility of power that is possible only among Sixes—and rare even there.

Vibration is Power Thrown Away

Vibration is wasteful as well as uncomfortable. It is power and fuel thrown away in joggling the car which should be used in propelling it. It throws useless strain upon bearings and tires It means discomfort for the passengers, and increased fuel bills It means the very life of the car cut short.

And vibration can't be cured by a makeshift. The only escape from it is in a six cylinder motor, where the impulses overlap; where the flow of the power stream is continuous.

The easy gliding motion of the Chalmers Six is like a caress. You who have never driven a real Six know nothing of its charm.

A One Motion Starter—A Non-Stallable Motor

One swing of a switch at the outset—and this is what happens. The Chalmers-Entz electric starter spins the engine to start it.

But that isn't all. If some unusual demand upon the engine should cause it to falter, the starter keeps it running until it picks up again.

There's no chance to be stranded in a throng or on a dangerous crossing. It makes the motor unstallable. In simplicity and sureness, the Chalmers-Entz system is without a parallel

The Test That Tells the Tale

The true measure of value and the only one—is performance. What will the car do in service?—that's the question.

So we have arranged the Chalmers Road Test We make our appeal for the Chalmers Sixes through the cars themselves We submit the evidence of deeds rather than of words.

Make this test it is more than just a ride Put the burden of proof on the car itself. It can't conceal; it can't exaggerate It will give you a new standard by which to judge other cars

The Master "Light Six" $1800

I am the Chalmers Light Six.

The son of a king—the Master Six.

I am like my illustrious sire though built in a lighter mould. I have speed—more than you'll need. Though my master motor is light I have power to spare. Light on my feet, I am saving on tires and frugal with fuel. I am easy to buy and easy to keep.

Six-Cylinder Value--Four-Cylinder Price

Many have waited for this day to come They want a car of low first cost, yet a car of generous size and ample power A light car, but not a little one But this car must be a Six For they know that means a car easy to ride in, easy to run, and easy to keep In the Master Light Six everything has been reduced to the simplest form yet nothing essential has been omitted It gives the luxury and economy of the Six at the price of a "Four"

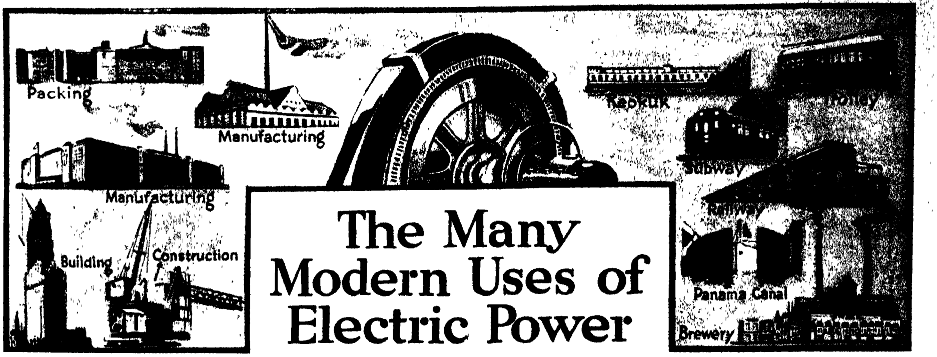
Safety First Always

When you ride in the light Six you can trust it Frame and axles are of heat treated steel with a four fold margin of safety Gears and roller bearings have withstood a crushing test of fifty tons Its brakes will stop it within its length Its electric starter prevents the motor from going dead at a critical moment The gears lock themselves in mesh The shifting device won't let you go wrong The assurance of safety is the corner stone of motor pleasure

Look at these features and try to match them at the price

- Six Cylinders
- Molded Oval Fenders
- Non Stallable Motor
- Electric Lights
- Triple Heated Fuel
- Timken Roller Bearings
- Locked Transmission Gears
- Chalmers Sectional Piston Rings
- Multiple Disc Clutch
- Underslung Springs
- 48 Horsepower
- 126 Inch Wheel Base
- Electric Starter
- Clean Running Board
- Tungsten Steel Valves
- Left-hand Drive
- Center Control
- 34-Inch Wheels
- Rayfield Carburetor
- Invisible Hinges
- Streamline Body
- Tapered Bonnet

Chalmers Motor Company, Detroit



The Many Modern Uses of Electric Power

FROM one end to the other of this busy country electricity has been demonstrating its pre-eminence as the smoother and the booster of business. In large manufacturing plants and small, in production centers of an immense variety, in public works and private enterprises—in every situation where POWER is needed—electricity has been proving its twentieth century utility. It has increased light and good cheer by eliminating line shafting and substituting individual motor drive. It has reduced fire dangers and insurance rates, and accident danger to workmen. It has promoted cleanliness. It has reduced power costs and proved its economy in related ways by simplifying operation, eliminating complexities in labor.

The Curtis Turbine has become a strong factor in power generation and the great range of G-E Motors has enabled these splendidly modern devices to meet all the intricate requirements of power transmission today. The partial list on this page will suggest the remarkable scope of usefulness in G-E apparatus.

Amoskeag Mfg. Co.
Manchester, N. H.—Largest cotton mill in the world—produces 60 miles of woven cloth an hour uses G-E Motors throughout.

Anheuser Busch Brewing Co.
St. Louis. Mo.—G-E Motor drive is used extensively in this well known brewery.

Buick Automobile Co.
Flint, Mich. When operating at full capacity this plant can produce a car a minute. G-E Motors used of course.

Cascade Tunnel,
Great Northern R. R.—G-E *Electric* Locomotives haul the trains through this famous tunnel.

Catskill Aqueduct,
New York City's water supply—practically all the electrical equipment used in constructing this famous aqueduct was furnished by the General Electric Company.

Great Southern Lumber Co.
Bogalusa, La.—Largest lumber mill in the world uses G-E Motors exclusively.

Indiana Steel Company,
Gary, Ind.—Hundreds of thousands of horse power from G-E Motors in this largest steel mill in the world.

Mississippi River Power Co.
Keokuk, Iowa—Largest power generating equipment in the world—G-E Electrical equipment throughout.

New York City Traffic—
No steam locomotives are allowed on Manhattan Island. G-E Electrical equipment is used by the N. Y. Central, the Interboro Elevated and the Hudson and Manhattan Tubes.

Panama Canal—
G-E Motors have helped to build and will operate the finished canal.

"Round the World"
-Every year the General Electric Company puts out enough railway motors to operate an electric belt line around the world.

Universal Portland Cement Co.
Buffington, Ind.—Operated by power furnished by G-E Motors.

Warner Sugar Refinery Company,
Edgewater, N. J.—Uses G-E Motor power extensively for all operations in connection with the refining of sugar.

The Guarantee of Excellence on Goods Electrical

Trade Mark

Wood Worsted·Mill—
American Woolen Company, Lawrence, Mass.—G-E Motors used throughout this largest Worsted Mill in the world.

Woolworth Building,
New York City—Highest office building in the world erected by G-E Motor-driven hoists.

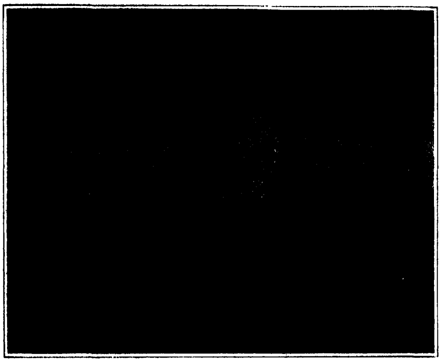

Fig. 1.—A waterspout located out in the ocean, about eight miles from Beaufort, N. C. The spout is almost vertical.

Fig. 2.—The same waterspout, its inclination being less vertical. The altitude of this meteor is two thousand feet.

Waterspouts

THE accompanying photographs show a waterspout observed near Beaufort, N. C., in the early part of August, 1911. It was one of four or five seen on the same afternoon in the same general region. At one time three of these rather rare phenomena were in view at once, but when the pictures were taken the two smaller ones had broken.

As nearly as could be ascertained, the base of the spout was located out in the ocean some six or eight miles from Beaufort. Its height, which was calculated from the size of the photographs taken with an eight-inch (focal length) lens at an estimated distance of six miles, was about 2,000 feet. It remained in view for nearly half an hour and, before it finally disappeared, nearly the entire population of the city had assembled at the water's edge to see the remarkable sight.

According to the fishermen, waterspouts are not uncommon during the late summer, but they very rarely assume the immense size of this one or have its sharply defined outlines. It is still more unusual for one to remain so long unbroken.

The day on which the observations were made was not different, perceptibly, from other summer days until late in the afternoon, when very heavy storm clouds began to gather in the west. They moved slowly eastward, and, when they had come to cover about three fourths of the western sky, a slender waterspout was seen in the far distance, looking like a column of smoke from some factory chimney. It broke soon after it was first seen.

It was next noticed that a pencil of cloud much nearer at hand, was gradually extending itself downward. Its progress was very slow, and at times it became so attenuated that it seemed to consist of separated pieces. As it approached the water it became slightly thickened, and when it finally appeared to reach the surface of the ocean, its outlines became sharply defined. A great cloud of vapor surrounded the foot and large masses, looking like the steam puffed out by a locomotive, slowly traveled upward to be lost in the tumbling mass of clouds at the upper end of the spout. The upper end was of considerably greater diameter than the middle of the column, but there was very little evidence of the violent rotary motion or the swift rush across the water that the books usually describe. A slow swaying of the column from side to side was all that could be noticed. A closer view, however, would doubtless have shown that the rotary and progressive movements were very rapid At times the column would become very tenuous, but the next minute would again become thick and dark After about twenty minutes had elapsed it gradually became thinner and thinner, broke, and the upper third was slowly drawn upward while the lower part was dissipated by the wind A heavy rain followed almost immediately

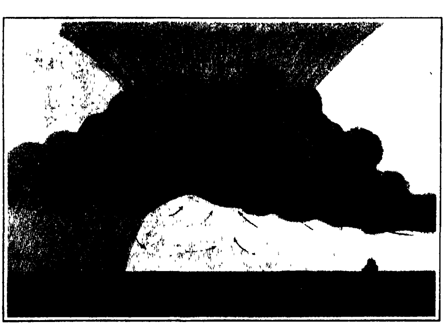

Fig. 3.—Cross-section of a thundersquall (after Arrhenius), showing the circulation of the air currents about a horizontal axis. According to Wegener, if the end of the whirl assumes a more or less vertical position it constitutes a "spout." A violent "spout" on land is a tornado.

Many popular delusions prevail on the subject of waterspouts: as, for example, the belief that they are actual columns of water, sucked up from the sea, and that they may be dissipated by firing a cannon ball through them. These and other errors were fully discussed in the SCIENTIFIC AMERICAN of June 10th, 1911, page 564.

When a French or German writer has occasion to refer to the class of atmospheric whirls to which belong the waterspout, landspout, and tornado, he calls them by the convenient generic name *trombes* (French) or *tromben* (German). The equivalent English word "spout," which was in common use in this sense a hundred years ago, is now so rare that a writer hesitates to use it, without an explanatory note. The French word *trombe* has often been borrowed by English writers, but is hardly in current use The revival of the word "spout" in scientific and general literature is a desideratum

Dr Alfred Wegener of Marburg has recently published in the *Meteorologische Zeitschrift* a novel hypothesis as to the origin of spouts The fact that these whirls begin in the upper air, and are not primarily due to conditions prevailing at the earth's surface, has long been known to meteorologists, though inaccurate statements on this subject are commonly met with in *soi-disant* scientific literature There is no indraft of the lower air from all sides, as in a cyclonic storm, the spout works downward from the clouds, and if it extends as far as the surface of the land or the sea it disturbs the air over only a small horizontal area just below it

Dr Wegener believes that the spout is always merely the attendant of a thundersquall, i e, an atmospheric whirl on an elongated horizontal axis The end of such a whirl is, according to this view, sometimes tilted downward until it reaches the earth, constituting a spout It is pointed out that the axes of spouts are usually inclined at a considerable angle, rather than vertical Even when the position of the axis approaches the vertical, it is often seen to be inclined in its upper portion toward the neighboring thunderstorm, a physical connection with which is thus suggested

There are few trustworthy observations of the direction in which the air rotates in a spout Inspection of the *debris* left by a tornado furnishes the only satisfactory evidence on this subject, and on this basis it has generally been believed that there was no constant rule for the rotation of a spout, as there is for that of a cyclone As the wind in a thunderstorm blows outward from the front of the storm at the ground, curves upward, and finally blows back into the storm to complete its circuit, if Dr Wegener's hypothesis is correct, the direction of the spout's rotation will depend upon whether the spout is formed at the left or the right side of the thunderstorm In the northern hemisphere spouts will usually form on the left side of thunderstorms. The right-hand deflection of the winds with ascent causes the storm to build itself toward the right and die out to the left, but a vortex, instead of participating in the bodily movement of the latter, is left behind as the storm shifts sideways.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Extensions of the Food and Drugs Act

ONCE upon a time the histrionic exhibition of candor on the part of a certain soap-making concern which announced that its product was only "99½ per cent pure" attracted considerably more attention than far more damnatory confessions of the same nature do to-day.

The Food and Drugs Act in these United States, and analogous legislation in other countries have wrought a remarkable revolution in the attitude of the public toward many things that were once regarded as "impurities" and "adulterants," and were accordingly in strong disfavor. Artificial coloring matter, preservatives, and the like have been to a certain extent robbed of their terrors. But the end is not yet. The last report of the United States Bureau of Chemistry traces the operation of two recent amendments to the Food and Drugs Act, which not only are significant in themselves, but open up new vistas to the student of practical ethics. The Sherley amendment, enacted August 23rd, 1912, deals with medicines branded with false and fraudulent statements concerning their effects on disease. Hundreds of these preparations have been analyzed by the chemists of the Bureau. As a result seizure of several preparations was recommended, and the prosecutions which followed were all won by default. Already a vast improvement in the labeling of medicines has resulted. The long familiar claims, "a sure cure," "a reliable remedy," etc., are being replaced on the labels by much more modest statements, such as "will be found beneficial in" or "will relieve many of the symptoms of." Fewer nostrums than formerly are alleged to be cures for such serious diseases as tuberculosis and cancer. The second amendment, known as the net-weight act, which dates from March 3rd, 1913, requires that all packages shipped in interstate commerce shall be plainly and conspicuously marked to show the quantity of the contents. Although effective from the above date, this law provides that no penalties shall be imposed for 18 months, and the Bureau confesses that it may be years before all the necessary data have been collected to insure equitable enforcement. Elaborate studies are now being made of such problems as shrinkage, variation of containers, errors in weighing, measuring, and counting by hand or machinery, i. e., the factors that may defeat the best intentions of the manufacturer to comply with the provisions of the law. For the study of shrinkage, experimental shipments of a great variety of goods are being made to detect changes in weight and bulk due to variations in temperatures and humidity, and the normal water content of foods is being investigated.

The Central Electric Companies' Problem

THE central electric companies have lately awakened to face a serious problem, the successful solution of which is essential to their future welfare.

The typical central electric company, a public service corporation, has but few electric generating stations. These, however, are large and economically located, usually on a river bank, so that water and coal costs, which are large factors in generating cost, may be reduced to a minimum. The prime movers are of the most efficient, and therefore most expensive type. Automatic devices, conveyors, etc., reduce the operating force to a degree that is surprising to the uninitiated.

At first glance one who had not investigated the proposition, would say instantly that a small private plant could not compete with a central plant such as is outlined above. If relative generating costs were the only consideration the private plant would at once be tabooed. The real features to be considered, however, are "What will it cost to generate the required power in a private plant?" and "At what rate could this power be purchased from the central electric company?"

The cost of generation, or power plant operating expense, represents less than twenty per cent of the expenses of the central company. The other expenses include taxes on property and lines, electrical losses on the company's lines (about one third the power sold because of leakage, etc.), interest and depreciation on equipment, advertising expenses, selling charges, uncollectable bills, and interest on bonds and stocks. The private plant expenses include only interest and depreciation on equipment, and cost of operating plant.

The above statements explain primarily why the private plant of a large building can compete with the central power company, but there is a secondary reason which is quite as important. A large amount of steam is required in large office buildings, apartment houses, hotels, etc., for various purposes. The heating system requires steam for approximately half the year, and the laundry, the cooking and refrigerating systems of the restaurant, and the hot water service require steam throughout the year.

Strange as it may seem, a private power plant supplying electricity and exhaust steam for the above purposes requires but little more coal than would be required for boilers supplying only the steam required for the building, no electricity being generated. This fact is due to the large amount of energy in the exhaust steam, the engine utilizing only about five per cent. The highly efficient engines of the central power company utilize about 17.5 per cent of the energy in the steam, or in other words, the private plant requires three and a half times as much coal to generate electric power as the central company. Add to this the greater coal, water, and attendance charges for a small plant and the two propositions appear to be on a par if only the electricity is considered.

If, however, electricity is purchased from the central electric company, boilers must still be operated to supply the necessary steam for the building. Much of this steam could be obtained from the engine exhaust of a private plant, and that is why the private plant of a fair-sized building is a paying proposition.

Allowing for the cost of operating boilers to supply the steam for the building, the cost of electricity for the year with a private plant of fair size would be only 40 to 70 per cent of the cost of electricity purchased from a central electric company.

That the actual condition of affairs is known to building managements is shown by the following statistics published in technical journals of recent years.

Buildings—Per Cent Having Private Plants.

Office buildings of twenty-six cities	63
New York buildings over eight stories high and occupying area over five thousand square feet	70
New York hotels, two hundred rooms or over, more than ninety in number	95

Many large buildings would install a private plant, but owing to the layout of the building, etc., a private plant never having been considered when they were constructed, they are limited to a heating plant.

The central electric company's field is limited to the buildings just mentioned and the small consumers. The problem of the central electric company is to increase its field of operation, or expressed in other words, to reduce the price of power to the consumer and yet obtain a good profit.

Two propositions are being considered by central electric companies to bring this about. The first is to use the exhaust steam of the engines of their plants for the manufacture of ice. Objections may be made to this on the ground that in winter, when the demand for ice is a minimum, the load, and therefore the amount of exhaust steam to be utilized, is a maximum. In summer these conditions would be reversed. Granting, however, that the ice plant would pay the operating expenses of the electric generating plant, the price of power to the consumer would not be radically lowered, for, as already stated, the cost of generation is less than 20 per cent of the expenses of a central company.

The second proposition considered is to establish a number of small power plants in buildings in the business section of the city and sell both electricity and heat to the surrounding buildings. A plant of this nature could not be operated more economically than a private plant, and would have the additional expense of its share of the advertising, selling, loss by uncollectable bills, and interest on the bonds and stocks of the company. The capital necessary to carry out this scheme would be enormous, as it would mean the complete revision of the electrical system, and as is indicated above, its efficacy would be very doubtful.

Evidently neither of the above plans is a successful solution for the problem, and even though the central electric companies should go into the ice business, the private power plant would still be a good investment for a building of reasonable size.

Economy in the Philippine Weather Bureau

THE ways of the powers that be in dealing with scientific institutions often give rise to extraordinary situations. The latest illustration of this fact comes to us from Manila, where on December 18th the veteran director of the Philippine Weather Bureau, Father José Algué, appeared before the Philippine Commission and, after pleading for two hours, succeeded in persuading that enlightened body not to impose upon the staff of his bureau a choice between starvation and the abandonment of their work. A poignant climax was reached when the director, who, with all his scientific skill and learning, is the embodiment of simplicity and sincerity, offered to relinquish the whole of his own salary, if his faithful subordinates might thereby be saved from a reduction of pay; an offer that is recorded to have produced "heart throbs" among his official auditors. The scene is thus described in a Manila newspaper:

> "It was a picture not soon to be forgotten by those who were present at the afternoon session of the Commission yesterday. It was the picture of a man who has devoted his life to a great work, who has sacrificed much that he might benefit not only the Philippine Islands, but the whole world by the results of his researches. It was the picture of Father Algué pleading with the law-makers that the work which has meant so much might continue and that, at his own sacrifice if need be, some trifling recognition of faithful services be accorded to his subordinate co-workers."

As everybody knows, the policy of the new administration in the Philippines is to reduce the expenses of government; in other words, official salaries. It is not yet clear just how the present upheaval is going to affect the large and able body of scientific workers who have been attracted from America and other countries to take service under the Philippine government, and accordingly we refrain for the present from discussing this phase of the subject. The employees of the Philippine Weather Bureau, however, are in a class by themselves. They may be regarded as permanent inhabitants of the Philippines and are not influenced by mercenary considerations in the choice of their field of labor. The director and a few of his chief assistants are Jesuit priests; the rank and file are natives.

The institution which ultimately became the Manila Observatory was founded by the Jesuits in 1865, and from the beginning has devoted itself especially to the task of protecting the islands from typhoons. Numerous outlying stations have been established from which reports are telegraphed daily to the observatory, where they are charted with reports from stations in Japan and on the China coast. Far to the eastward telegraphic outposts have been established in the islands of Guam and Yap. With its broad outlook, the mature experience of its officials, and facilities for rapidly issuing warnings by wire and wireless, not only to all parts of the archipelago, but also to vessels upon the high seas, the observatory is recognized throughout the Far East as an absolutely indispensable means of safeguarding life and property from the dreaded typhoons, of which, in an average year, about twenty-five actually enter the Philippines, to say nothing of many others which sweep across the adjacent seas. Incidentally, this meteorological service has compiled the climatic statistics necessary for placing scientific agriculture in the Philippines on a sound basis; has made a systematic study of earthquakes, volcanoes, and terrestrial magnetism in the islands, and maintains work in practical astronomy.

After the American conquest the observatory and its network of stations were taken over by the new government, without any changes of personnel or organization, and were known thereafter as the Philippine Weather Bureau. The service is not in any way connected with the Weather Bureau of the United States.

The cost of maintaining this service, which was acquired without *any* initial expense, has been modest to the verge of absurdity. Especially in the matter of salaries has the history of the Philippine Weather Bureau been such as to delight the most parsimonious dispenser of public funds. In spite of a trifling increase in 1911, the average salary paid to each of the eighty-three employees who constitute the meteorological division of the service, counting in the relatively magnificent stipend of $2,500 drawn by the director, is approximately $385 a year. Some of these men have served for twenty-five years. All have proved faithful in the performance of arduous duties requiring more or less technical skill. Last but not least, if they should suspend their labors the unpreparedness of the islands for the first storm that came along might conceivably cost more in devastated property, not to mention the loss of life, than the entire expense of operating the bureau from its foundation to the present time.

Yet Father Algué only persuaded a thrifty legislature not to *reduce* the salary fund of his bureau!

Science

A Memorial to African Explorers.—On November 21st Lady Scott, widow of the Antarctic explorer, unveiled a tablet in the parish church of Cranbrook, England, to the memory of Lieut. Boyd Alexander and Capt. Claud Alexander, who lost their lives while exploring in Africa three years ago.

Spread of Gypsy Moth by the Wind.—Experiments conducted by the U. S. Bureau of Entomology prove that the newly-hatched caterpillars of the gypsy moth may be blown, under favorable conditions, a distance of six miles or more. Thus the wind is an important factor in the spread of this destructive pest.

Elliott Cresson Medal for Molecular Air-Pump.—The Franklin Institute of the State of Pennsylvania has awarded its Elliott Cresson Gold Medal to Prof. Dr. Wolfgang Gaede for his molecular air-pump, in consideration of the very great value of this invention for the quick production of vacua beyond those hitherto obtainable. A description of this pump appears on another page.

The "Fram," the most famous polar exploring ship in the world, will not, after all, have the honor of being the first vessel to pass through the Panama Canal. After waiting at Colon since October 3rd, she has now started south on the long journey to the Pacific *via* the Straits of Magellan. It was feared that an indefinite delay at Colon might prevent her from reaching San Francisco by the time Capt. Amundsen plans to start for the Arctic regions next Summer, in which case the expedition would have to be postponed for a year.

Pellagra and Stable Flies.—It is now generally supposed that pellagra is carried by some biting insect, and the buffalo gnat, among others, has been suspected. Investigations recently carried on in Spartanburg County, S. C., by the U. S. Bureau of Entomology and the Thompson-McFadden Commission of the New York Post-graduate Medical School, practically exclude the possibility of transmission by the buffalo gnat, but tend strongly to show the possibility of transmission by the stable fly, already known to be the carrier of several other diseases.

The Canals of Mars.—Prof. Lowell telegraphs to us from Flagstaff, as follows: "The canals of Mars are now exhibiting a very striking seasonal development from north to south over the planet surface, being darkest and strongest near the edge of the melting north polar snow cap and thence gradually pushing farther and farther southward. This is exactly in accordance with what the Lowell Observatory has predicted for their behavior from its extensive and critical study of the planet, and is corroborative of Lowell's theory. This observed development of the canals is somewhat similar to the annual inundation of the Nile."

The International Catalogue of Scientific Literature, published annually, in seventeen volumes, each devoted to a particular science, has recently completed its tenth year of publication and is regarded as an indispensable part of the working equipment of scientific libraries throughout the world. Although the volumes are issued by the Royal Society of London, the undertaking is truly international, representing the co-operation of 32 governments or national institutions. The committee of the Royal Society which has the oversight of this work is also engaged in completing the great Royal Society Catalogue of Scientific Papers, which covers the scientific literature of the nineteenth century and of which subject-indexes are in course of publication. All scientific workers will be dismayed to learn that there is grave danger of the suspension of this splendid bibliographic undertaking on account of lack of funds. An international subscription ought to be started at once to prevent such a calamity.

Improvements in Meteorological Instruments formed an important part of the work of the Weather Bureau during the last fiscal year, according to the annual report of the Bureau recently published. Investigations of anemometers were carried on with a view to the standardization of these instruments for measuring high wind velocities. A large motor-driven whirling machine having a horizontal arm 30 feet long and capable of being driven at all velocities up to 75 or 100 miles an hour, measured at the end of the arm where the anemometer is installed, was used for these tests at Mount Weather Observatory. Valuable data have been secured, but the investigations have been temporarily interrupted by the appointment of the official who was conducting them to the position of Chief of the Weather Bureau. Important progress has also been made in the revision of psychrometric tables. The most interesting instrument devised during the year was an automatically recording rain-gage, which can be left without supervision for a period of eight days and will make an accurate record of the rainfall during that period. An instrument of this character has been urgently needed for installation in places where it is impracticable to station a resident observer.

Automobile

Seats Heater in the Steering Wheel.—A steering wheel having in its face a recess is provided with a closure for the recess and an electrical heating unit is carried by the closure within the recess, the same being shown in a patent No. 1,082,830 to Rubin S. Smith of Marshall, Texas.

Air-brake for Motor Trucks.—An air-brake, so called, has been added by the manufacturers of a French motor truck as part of the regular equipment. The device is not what is generally understood as an air-brake in this country. It is more of a dynamometric fan, or fan-brake, similar to the mechanism employed in striking clocks. When the motor truck is on a long down grade on which continued application of hand or emergency brakes would burn the brake lining, the driver pulls the "air-brake" lever. The revolving shaft acts by means of a bevel gear upon a wide-bladed large fan mounted horizontally below the body of the truck. The resistance of the atmosphere to the forward motion of the fan blades retards the shaft revolutions sufficiently to brake the truck. Objection to the device has been raised because of the great tendency to whirl dust upward against the truck.

A New Binary Automobile Motor.—Something entirely new in the application of the binary vapor principle to automobile engines has been brought out by an English inventor. Condensed into its vital facts the new device is a four-cylinder motor in which the cylinder nearest to the radiator has been supplanted by a steam cylinder. The cooling water of the gasoline motor, when heated by the cylinders, is led into a compressor and subsequently forced into the steam cylinder where it is charged under pressure with the hot exhaust gases from the three gasoline cylinders. The pressure of the now superheated steam-gas mixture forces down the piston in the steam cylinder, which piston is connected to the crankshaft by the usual connecting rod. In effect the new motor is an engine with three cylinders of the internal combustion type, and a fourth cylinder in which the heat of the exhaust gases is utilized as pressure. The inventor claims a fuel reduction of about 20 per cent and a steadier running of the engine.

Power Consumption of Electrical Apparatus.—Since the general introduction of electric lighting and engine starting equipment on the modern automobile, the question of its power consumption has been a moot one. Manifestly, the figure must vary with varying equipment, and with different cars, but much light has been shed on the question by a number of tests recently made on the Long Island motor parkway. The tests were made with a six-cylinder five-passenger touring car weighing 4,862 pounds "all on" and driven with top up, windshield in place and side curtains on. The illuminating equipment consisted of ten lamps which were kept burning. The test was conducted by the Automobile Club of America. Four runs were made, two at 20 miles an hour with the generator in action and out of action, respectively, and two at 40 miles an hour under the same conditions. Briefly, the results revealed that whereas 7.3 gallons of fuel would drive the car 100 miles at 20 miles an hour with the generator not running, 7.6 gallons would be required with the generator in operation, at 40 miles an hour the gasoline consumption per 100 miles, without the generator running, was 8.7 gallons, and with the generator in operation, 9 gallons. The difference in fuel cost per 100 miles, at the average rate, is approximately six cents.

France Offers Prizes for Kerosene Engines.—By way of stimulating the use of kerosene as a motor vehicle fuel, for which the French automobile industry is convinced there is a great future, the Automobile Club of France, located in the French capital, is to hold a series of tests of kerosene engines commencing October 1st next, with prizes to aggregate $12,400; the first prize is $10,000, the second $2,000, and the third $400. The test is not a carbureter test, but is designed to demonstrate the usefulness, fuel consumption, etc., of four-cylinder engines rating between 20 and 30 horse-power, of the automobile type. Each engine entered, for which the fee will be $30 prior to April 1st and $60 after that date and up to July 1st, must not weigh more than 33 pounds per horse-power exclusive of fuel and water tanks. Engines can be started on gasoline, provided this fuel is not contained in a tank that forms part of the equipment. There will be four bench tests— three hours each at full and half load, two hours half full speed and two hours light—during which the fuel consumption must not exceed (for qualification) 350 grammes per horse-power hour. Subsequently, the engines will be placed in chassis the minimum weight of which is to be 14,040 pounds, for road trials which will cover four days, in which the vehicles will be driven 620 miles at an average speed of 19 miles an hour. Throughout the tests, paraffin having a density of 810–820 and a flash test (Granier instrument) of 35 degrees, will be supplied to contestants. Points from 0 to 20 will be awarded for performance, fuel economy and general operation, etc.

Astronomy

The Light of the Earth.—It has been remarked that the globular light from the whole sky is superior to the sum of all the quantities of light sent to us separately by the stars. Even the most sombre regions seem lit by a diffused light which truly has its origin in the terrestrial atmosphere. It is the light of the earth. Different people have endeavored to evaluate the intensity of this earth light and have found that it is of the order of one tenth part of the intensity of a star of the first order of magnitude. It is attributed, at least partially, to a permanent aurora borealis which is revealed by the characteristic green ray which is observed on obscure nights in the whole heavens. There is probably something else: the continual bombardment of the upper atmosphere by meteoric swarms and cosmic dust may also illuminate. The mass of meteoric matter which would suffice to explain the observed phenomena has been calculated and the figure found is in good agreement with that given by a direct calculation of the quantity of cosmic matter which strikes the earth.

Stars of Class B.—Stars of which the spectra are particularly marked by the lines of helium and hydrogen are designated as class B in the Harvard classification. The general opinion is that these stars are very hot, that they are of great mass, with a high pressure in the atmosphere that surrounds them. They are also regarded as very young in the order of their evolution; being preceded in this respect only by the stars of class *O*, which comprises relatively few stars. As the result of detailed researches by P. W. Merrill, it appears that the distribution in the heavens of stars with brilliant lines accords with that of all the stars of class *B*; they are even relatively more numerous among the stars of class *B* superior to the fifth order of magnitude, which seems to indicate that there is a greater chance of encountering stars with brilliant lines among the very big stars. There are also cases, the most remarkable being that of the Pleiades, where a certain number of these stars seem very closely grouped, and it is difficult to admit that these groupings are fortuitous.

The Constitution of Comets.—Great diversity of opinion has prevailed on the subject of the physical constitution of comets. It has been maintained, by different astronomers, that the nucleus of a comet is solid, is liquid and is gaseous. If we agree with Schiaparelli and see a relation between comets and the swarms of meteorites, it is difficult to avoid the conclusion that a comet is a cloud of solid particles, and we return to the theories of Prof. Newton, who regarded comets as veritable "sand-banks." What are the dimensions of these constituent particles? We do not know; we can only say that in all probability they vary in size from a grain of dust to a body of several cubic yards. However this may be, the particles are certainly separated from one another by great distances, and, speaking on a small scale, we may liken a comet to a number of particles about the size of a pin's head at distances of some hundreds of yards. Each particle carries with it a gaseous envelope formed principally of a substance furnishing a spectrum analogous to that of the hydrocarbons. Under the action of the sun, and perhaps through some electrical effect, the envelope becomes luminous or phosphorescent. This view of a comet's structure explains the fact that even the feeblest stars may be seen through the cometary cloud, without suffering either appreciable diminution in brightness or refraction.

The Age of the Earth.—Certain colored minerals, in particular certain micas, when examined microscopically, present dark stains in the form of a disk. At the center of each stain is a little crystal, usually a crystal of zircon which has been included at the moment of formation of the mica. The explanation of these dark stains is to be found in the fact that the zircons are strongly radio-active. The radio-active crystals stain the mica in the same way as they color glass, etc. But the x-rays emitted by different radio-active substances have not all the same penetrating power, and for that reason the mica stains are usually darkest at the center. If they are old enough the stain is uniformly dark, as even the few rays which reach the outer part have had time to completely stain it. Experiments were made by Joly and Rutherford to determine experimentally the number of x-rays required to produce a given stain in mica. Measurements were made on the halos or stains so produced and they were compared with those produced naturally by the zircon crystals. The amount of uranium present in the crystal was evaluated and the number of x-rays necessary to produce the natural stain permitted one to ascertain the amount of uranium which must have disintegrated since the origin of the mineral. The theory of radio-active transformations then leads very simply to an expression for the age of the halo. The numbers obtained oscillated between 470 million and 20 million years, which is in fair agreement with the determinations of the age of rocks, although they differ from the results which have been deduced from the quantity of salt contained in the oceans.

A New Way of Throwing Messages from Aeroplanes

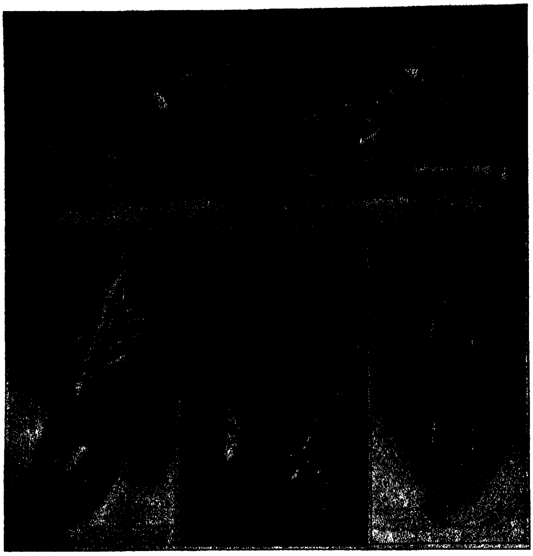
By Lucien Fournier

As the flying machine developed, the need of subsidiary apparatus became apparent. Military men soon demanded the installation of wireless apparatus, guns, armor and similar accessories. While a great deal of experimenting has been done to give them what they want, it can hardly be said that a very great measure of success has as yet been attained. Especially is this true of the wireless equipment. The sending apparatus which can be carried on an aeroplane is necessarily of very small range, and the receiving apparatus must struggle with the difficulty of interference. Some day these objections will undoubtedly be overcome, but until they are, a French inventor and aviator, Paul Fugairon, believes that some such apparatus as he has invented and tested near Brest will be more acceptable to military men. With his invention a message can be dropped in full flight by an aviator who is sufficiently near his destination, the craft returning immediately at full speed to the enemy's position There is no danger that the message will be blown away by the wind, or that it will be lost or damaged in mud, dust, high grass, and heavy foliage.

As the accompanying diagram shows, the apparatus consists of a hollow cylinder, in which the message is received. At its base the cylinder is inclosed by an ogival member *P* into which lead has been poured, so that the apparatus will always drop upon the point *P*, which passes freely through the lead. At the other end of the cylinder is a cover *L*, the top of which is formed like a lantern with four open windows *C*. Within the cover are four clamps to hold material for a Bengal fire. This is ignited by the explosion of a cap of mercury fulminate. As the apparatus strikes the ground, the cap is exploded by the firing pin *B*, which is guided in two brackets, and the flame of the explosion being conducted to the Bengal-fire material through the curved tube *U*. A lever mechanism here connects the firing pin *B* with the point *P*, the lever mechanism being held in a position of rest by the spring *R*. As soon as the point *P* penetrates the ground the spring *R* is compressed, the lever mechanism is operated to pull the pin *B* backward a short distance, and to release it immediately afterward The firing spring which was put under tension before the message was dropped, is thus liberated, so that the pin *B* is forced against the fulminate cap

The exceedingly bright Bengal fire which flashes up can be seen not only at night, but in daytime as well What is more, it burns long enough to allow a soldier who has been watching for it to cover a distance of 300 yards to the spot where it has fallen, and whither its light guides him

Obviously not only written messages, but also sketches and rough maps can be "canned" in this way



By means of this simple device messages can be discharged from an aeroplane with the certainty that they will be found. As soon as the device strikes the ground Bengal fire is ignited, and the resultant smoke indicates where the message is to be looked for.

Traveling Crane for Building Construction

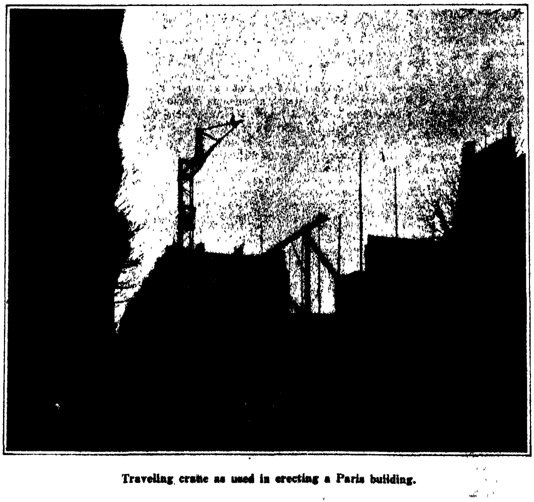
A NOVEL type of crane has been devised in France for handling materials in building construction. It consists of a lattice-steel mast mounted on four wheels, two of which run on a track placed on the ground parallel to the front of the building, and the other two on a track about forty feet above the ground. The latter is maintained in position by uprights and tie-rods secured in the mass of the building foundation. The construction is clearly shown in the engraving which represents one of these cranes in service on the Boulevard Malesherbes, Paris. The track is supported at frequent intervals, and is furnished with holes about four inches apart to provide for attaching it at places appropriate to the requirements of the building

The mast is constructed of angle iron spaced about four feet apart and stiffened with cross braces. The head of the mast carries a turntable set out from the center about four and one half feet so as to carry the load well into the interior of the building. The crane proper can make a complete revolution, thus avoiding accidents which occasionally occur in cranes that cannot make a complete turn, because in a violent windstorm the boom can set itself in the direction of the wind, like an ordinary weathervane, without coming in contact with any fixed portion of the structure.

The boom is arranged in such a way that the lifting block may be positioned in accordance with the weight of the mass to be lifted. For a weight of 1,500 kilogrammes (3,300 pounds) a reach of seven meters (23 feet) can be used, while the crane can lift 7,000 kilogrammes (15,000 pounds) at a distance of one meter (3.3 feet).

The mechanism of the crane includes in addition to the lifting gear means for propelling itself along the track and also means for swinging the boom. There are two lifting speeds operated by friction clutches. The transporting movement is accomplished by cone gearing and friction clutches. In order that the load may be properly served by the crane it is essential that the operator should be able to see the work which he is doing. For this reason the operator's cabin can be placed upon the mast at any required height, variable with the state of advancement of the work. The great advantage of this type is that it does not encumber the road. Half a meter (1.64 feet) is sufficient to secure the passage of the apparatus between the scaffolding on the one hand and the regulation scaffold on the other The height of the apparatus is variable. It has been used up to a height of 35 meters (115 feet), while the reach has been carried to 12 meters (39 feet). A special arrangement allows the use of the apparatus on an inclined path. In one case two cranes of this type were used in the construction of a viaduct on a 32 per cent slope.

In the case of a building on a corner, it is useful to be able to serve the two frontages by means of a single transporter mast crane. For this purpose a turntable has been designed, allowing the crane to pass from one frontage to the other in a few minutes.



Traveling crane as used in erecting a Paris building.

Citropsis

THIS name is given by W. T. Swingle and Miss M Kellerman to a new genus of tropical African fruits, which may be called generically in English "African cherry oranges." The species, of which there are several, were formerly assigned to the genus *Limonia*, under which they figured as the sub-genus *Citropsis* in Engler's classification. The authors above named find, however, that they are much more nearly related to *Citrus* than to *Limonia*, and this relationship opens up interesting possibilities for the plant-breeder. In their natural state some species of *Citropsis* bear an abundance of delicious fruit. Greenhouse experiments at Washington show that at least one of the species can be grafted readily on several *Citrus* stocks, while *Citropsis* serves as a successful stock for grafting grapefruit and oranges. Any new stock available for grafting citrus fruits is a lucky find, since it generally increases the range of soils adapted for the culture of such fruits and adds to the chances of combatting disease.

Whale Meat is becoming a more and more popular article of food in Japan, where it is not only sold fresh, but also canned on an extensive scale. Canned whale meat is used by the Japanese army as a field ration. The chief objection to its more general use appears to be its strongly fishy taste and odor.

A Great Brass Brain

A Unique Engine, on the Accuracy of Which Depend Millions of Dollars and Thousands of Lives

By C. H. Claudy

ROGER BACON, man of letters and of science, who lived in the thirteenth century, is supposed to have manufactured a brazen head or android, which spoke and revealed "dreaded secrets of the past and future." But no brass brain has come down to the present day from antiquity which can even think, let alone articulate through a brass mouth.

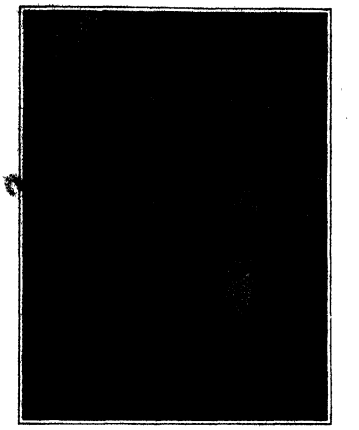
But a mechanism, built for these United States of ours, can truly be called a "brass brain," in that it does the mathematical calculations which would otherwise require a hundred flesh and blood brains to do; and if it does not actually articulate its results, at least it indicates them plainly enough, not only by dials, but by writing them down. Still more does it claim kinship with that ancient and fabled brass brain of Bacon's, in that it, too, foretells the future, though no "dread secret" does it make known.

This introduction may seem fanciful—it is sober fact. The machine is known as the United States Tide Predicting Machine, Number 2. It is in daily operation in the United States Coast and Geodetic Survey at Washington. Its work is nothing less than the predicting of the times and heights of high and low tide, a year in advance. Its mechanism is of brass and steel, its house a huge mahogany and glass case, and its tender one observer, who does but sit and turn a crank until it stops, then copies off on paper the reading of several dials, and later removes from the machine a roll of paper on which is plotted the tidal curve for the particular spot along the coast, the tides of which have been predicted.

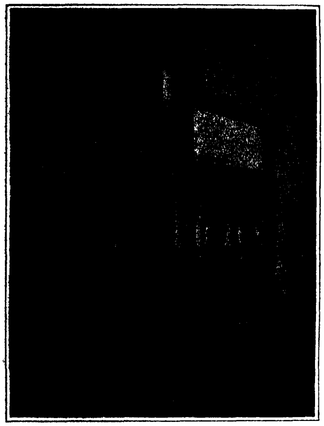
Every year the United States issues a fat book of Tide Tables, primarily for the use of its navy, and secondly for the use of all who go down to the sea in ships. This book of Tide Tables gives the time to the minute and the height to the nearest tenth of a foot of every high and low tide during the year for seventy of the great world seaports, and by means of an auxiliary table, the same information for 3,000 other places.

It is essential for the mariner to know when tide is high and when low, and the magnitude of the tide. The safety of his ship and the lives of all on the vessel may depend on that information being accurate and reliable. So that when it is a question of predicting for some day in the future, just when high water will be reached in New York harbor, or when low tide will occur in the Golden Gate, and just how high or how low the tide may be, you can be very sure that the machine which prophesies is an accurate if complicated machine. That it is a wonderful machine may be imagined. It has over 15,000 parts, but so carefully is it made that lost motion is reduced practically to zero. Unlike the human brain, this one of brass cannot make a mistake. How wonderful this is, it is difficult to conceive without some knowledge as to how a tide is actually produced and how it would be predicted by the use of pencil and paper alone—the oldest way known, and also the longest and least accurate.

As most people know, the tides are the names we give to those periodical risings and fallings of the ocean which occur daily. They are produced by the action of the force of gravitation between the sun and moon and earth. The tides are thus the result of forces which come under observation of the astronomer, and it is astronomical data which is used in predicting a tide.



Where tidal component differences are gathered together.



Front view, showing controls, dials and tidal curve plot.

Side view of the tide recording machine, showing the pulleys and chain that govern the movement of the pen.

If the earth was a perfect sphere, covered all over with water to a uniform depth, if the earth went around the sun in a circular path with the sun in the center and the moon went around the earth with a perfectly uniform motion and if sun, moon and earth were always in the same plane, tide prediction would be a simple matter of mathematics; the heights of a tide for all ports in any one latitude could be made together

But the earth is *not* a perfect sphere. It *isn't* covered with water to a uniform depth, it has many continents and islands and sea passages of peculiar shapes and depths, the earth does *not* travel about the sun in a circular path, and earth, sun and moon are *not* always in line. The result is that two tides are rarely the same for the same place twice running, and that tides differ from each other enormously in both times and in amplitude

For many years tide predictions were made, entirelv by manual and mental labor, and because of the complication of the matter, but few of all the causes which enter into a tide were considered in actually predicting how high a tide would be, and when it would be in flood.

But Sir William Thompson now Lord Kelvin, revolutionized matters when he devised what he termed a system of "harmonic analysis." It is evident that if a pencil be made to rise and fall as the tide rises and falls, on a vertical sheet of paper which moves under the pencil, a curve will result. It is also evident that if a sufficient number of observations are made to get rid of those tides which are late or early because of wind, or high or low because of freshets on land, the remaining tide curves, if averaged, will bear a definite relation to the actual tidal causes Sir William Thompson found that he could analyze these tidal curves.

He began by imagining a fictitious sun, which moved evenly in a circular path about the equator at a uniform speed. The real sun doesn't move that way at all But the theoretical sun, being a figment of the imagination, did as it was told. To this obedient sun was added another sun which moved differently, and still another moving still differently, and so on, until a very respectable number of imaginary suns were circling about the earth. These suns were all so calculated that the sum total of their attractions and movements equaled the sum total of the attractions and movements of the real, sure enough sun! Instead of having one sun in an irregular number of positions and distances, Lord Kelvin imagined a number of perfectly regular suns, which did what they were told as to unvarying motion, but which, when combined, equaled our own irregular sun

The same thing was done for the moon; and behold a whole lot of definite, regular, undeviating mathematical factors, *all together equaling the puzzling irregularities* of our real sun and moon, but separately so well behaved that they could be used all the time as components of a mathematical equation which would demonstrate a tide

All the most important of these theoretical suns and moons, or components of the tides, as they are called, were computed by Sir William Thompson and extended and improved by Sir George Darwin, brother of the great Darwin Since that time, these components of the tide have been computed for practically all the important tide stations in the world and are common property.

It didn't take Sir William Thompson long to figure out that if harmonic analysis could predict tides from data gathered from an observed tidal curve, then the components which could be extracted from a given position of sun, moon and earth ought to be able to be put into a tidal curve. From this was but a short step to actually making the first tide machine, which took account of but ten components of a tide, but actually plotted a predicting tide curve

This first tide predicting machine was followed at intervals by four others, two for England, one for France and one for Brazil But conceiving a tide machine is one thing, making one practical, another, and all the various machines failed to take account of any great number of tidal components Then came Prof. William Ferral of our own Coast Survey, who, in 1881, designed a tide predictor which was used by the Coast Survey for twenty-seven years It was the first tide predicting engine to show on dials on its face the time of day, time of year, height of tide, etc Instead of producing a tidal curve, it required only that an observer copy off the data to have it ready for the printer. All the other machines had traced curves from which a calculator had to work, digging out, literally by its roots, the data in numbers, from the curve in front of him.

The underlying principle of all these tide predicting machines has been the same—the summing up mechanically of a number of different motions, actions and reactions. The means is a slender chain, passing over pulleys, each of which is mounted on a shaft or crank The crank is adjustable, so that it can be made more or less eccentric with the shaft itself The degree of eccentricity represents the amplitude of the particular component (or imaginary sun or moon) of the tide under consideration. When the machine is operated, the various cranks revolve, and the chain which passes over them all is pulled upon by some and allowed to become slack by others The movement of the end of the chain, then, becomes the sum of all the movements of all the components in the machine, each represented by a crank, adjustable on a dial.

By attaching the end of the chain suitably to a pen, and by having a moving sheet of paper beneath the pen, the machine traces the tidal curve. The principle of this mechanical summation is illustrated in the diagrammatic sketch, in which five component slides are shown Reference to the photographs will show how these are operated; an adjustable steel crank-pin on each disk or wheel works in a horizontal slide in a light steel frame, an extension member of which terminates in a pulley, *C*, *D*, *E*, *F*, and *G* Passing over and under these pulleys is the steel chain of the apparatus, one end of which is fixed (4 in the diagram) and the other end of which is suitably connected with a movable pen *B*, which plays against a ribbon of paper that passes beneath it.

If we suppose the disks 1, 2, 3 and 4 in the diagram are fastened and stationary, and imagine a counterpoise weight connected to the chain beyond the pen *B*, then it is obvious that if the disk 5 revolves and at the same time the ribbon of paper passes from right to left under the pen, a true harmonic curve will be produced as in the line *ZZ* (of course the curve will be a solid line in practice; dotted lines are here used for clarity).

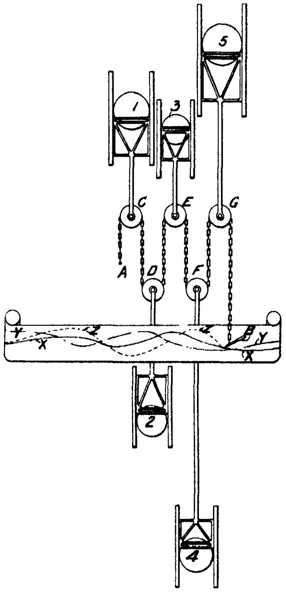
If now we suppose the disks 1, 2, 3, and 5 to be fixed and immovable, and disk 4 to revolve, another type of curve will be produced on the moving sheet of paper, as in the curve *YY*.

Now if disks 1, 2, and 3 be kept fixed and immovable, but disks 4 and 5 are permitted to revolve, then the curve traced upon the paper will be the sum of the two curves *ZZ* and *YY*, as shown in *XX*. If all five of the disks revolve, then the resulting curve will be the sum of all their curves individually.

If each disk in its speed of revolution represent the effect of motion of a lunar or solar component of a tide, and each crank on each disk is set so that its distance from the center represents the amplitude of such motion, then each disk, crank and slide truly represents a *factor* of a tide—the effect of one of the fictitious moons or suns, the sum total of the motion of which expresses the tide itself.

The Ferral machine was wonderful and accurate for a while. But it wore badly with years of use, its slender shafts were not sufficiently rigid to keep an *error of torsion out of the results, and it was decided* after twelve years that a new machine, better and quicker, more accurate, and more reliable, should be made.

Mr. E. G. Fischer worked upon the Ferral machine Later he became Chief of the Instrument Division of the Survey. When it was decided to build a new machine, it was to Mr Fischer that the authorities turned. *He designed a new machine, and after the plans* were accepted, went to work Only such time as could be spared from the regular work of the Instrument Division was put into the new machine, which was fifteen years in building. But now it is finished, and stands forth as the most remarkable, most accurate and most complete machine of its kind in the world. It takes account of thirty-seven factors or components of a tide. It is truly American in its design, for not only does it do what all the foreign machines have done, plot a tidal curve by pen and ink, but it does also what the Ferral machine did—presents the results on dials for visual reading. It not only gives the times of high and low tide, but shows by a time line on the tidal curve sheet the hours, so that the state of the tide at *any* time can be readily computed



How the curves are summed up mechanically.

The machine is entirely automatic, once it is set The observer sits at the end, and turns a crank. When it will turn no farther the hands point to the day, the month, the hour, the minute, and the height in tenths of a foot of the tide. Pressure of a button in the crank releases it, and the next stop indicates the same data for the next tide. All the time the machine is doing this it is also tracing out the tidal curves, which are filed away for reference, so that should any question arise as to the figures as the operator takes them down, the machine need not be reset to get them over again; reference to the tidal curve will show all that the machine has shown

The machine is two sided; one side has the tidal fluctuations to care for, the other, the time, so that when the prediction is made, it is complete. The copy, as it is made from the machine by the observer, goes directly to the printer, ready to be set up and printed.

Mr. Fischer strove long for some scheme by which a mechanical means of summation could be obtained which would eliminate a chain. Always he came back to it as the most practical. Every single thing about this wonderful machine was made by the Instrument Division (castings for the base are excepted) save the chain, which is fine chronometer chain, imported from England. To be sure that it was properly stretched, and worn and smooth in its actions, Mr. Fischer ran it in an endless belt form, over dozens of pulleys of all sizes, on the walls of his workshop, driving it eight hours a day by electric motor for months and months. It was bent in every link, not hundreds, but thousands of times, until, when it was put in the completed machine, it had done all the wearing possible.

As an instance of the extreme accuracy of the machine, Mr. Fischer told the writer of some tests which were made of it.

"We picked out two stations for these tests," said Mr. Fischer, "which we believed would most thoroughly test the machine because of the complicated nature of their tides These stations were Aden, Arabia, and Hong Kong, China For Aden we used thirty-five components of a tide and for Hong Kong thirty-three.

"We started the predictions at the beginning of a year and ran the machine until it had predicted the tides for almost the whole year at both these places. Not until then did we take a reading. Then we read the prediction for a given day. When we compared this reading, which had come after the machine had had a chance to add up infinitesimal errors through a year's predictions, with that of the most careful and accurate human calculation, we found a maximum error of 0.02 of a foot for the Aden tide, and 0.06 of a foot for the Hong Kong tide."

To do the same work in the same time, taking in the same number of factors or components, would require one hundred men. One wonders whether they would be anywhere near so accurate as the great brass brain.

The machine bears upon its face, by order of the Superintendent of the Coast and Geodetic Survey, the legend "Designed and constructed by E. G. Fischer." It is a monument not only to those men who went before—Lord Kelvin and Prof. William Ferral—but to the gentleman whose profound knowledge of mathematics, skillful ability in instrument work, and cleverness as a designer, made possible the greatest and most remarkable calculating engine in the world.

The Quantum Theory of Energy

THE old controversy so beloved of the Greeks as to whether matter is continuous or discontinuous is in our day definitely resolved in favor of the latter view. It is true that the ultimate particles of matter are considered to be something in the nature of local modifications of the ether, but nevertheless, matter as matter has a discrete structure This tendency to atomize has now been imported into the conception of energy. At first sight it would seem that energy is something necessarily continuous, but it is found that this assumption leads us into serious difficulties. It is by examining the phenomena of heat and light radiation from bodies that scientific men have been led to adopt the remarkable hypothesis which postulates an atomic structure for energy.
